3. Helmholtz first solved the problem—Given the spin in any case of liquid motion, to find the motion. His solution consists in finding the potentials of three ideal distributions of gravitational matter having densities respectively equal to $1/4\pi$ of the rectangular components of the given spin; and, regarding for a moment these potentials as rectangular components of velocity in a case of liquid motion, taking the spin in this motion as the velocity in the required motion. Applying this solution to find the velocity in our Secondary from the velocity in our Tertiary, we see that the three velocity components in our Primary are the potentials of three ideal distributions of gravitational matter, having their densities respectively equal to $1/4\pi$ of the three velocity components of our Tertiary. This proposition is proved in a moment,¹ in § 5 below, by expressing the velocity components of our Tertiary in terms of those of our Secondary, and those of our Secondary in terms of those of our Primary, and then eliminating the velocity components of Secondary so as to have those of Tertiary directly in terms of those of Primary.

4. Consider now, in a fixed solid or solids of no magnetic susceptibility, any case of electric motion in which there is no change of electrification, and therefore no incomplete electric circuit; or, which is the same, any case of electric motion in which the distribution of electric current agrees with the distribution of velocity in a case of liquid motion. Let this case, with velocity of liquid numerically equal to 4π times the electric current density, be our Tertiary. The velocity in our corresponding Secondary is then the magnetic force of the electric current system;² and the velocity in our Primary is what Maxwell³ has well called the 'electro-magnetic momentum at any point' of the electric current system; and the rate of decrease per unit of time, of any component of this last velocity at any point, is the corresponding component of electro-motive force, due to electro-magnetic induction of the electric current system when it experiences any change. This electro-motive force, combined with the electrostatic force, if there is any, constitutes the whole electro-motive force at any point of the system. Hence by Ohm's law each component of electric current at any point is equal to the electric conductivity multiplied into the sum of the corresponding component of electrostatic force, and the rate of decrease per unit of time of the corresponding component of velocity of liquid in our Primary.

5. To express all this in symbols let (u_1, v_1, w_1) , (u_2, v_2, w_2) , and (u_3, v_3, w_3) denote rectangular components of the velocity at time t , and point (x, y, z) of our Primary, Secondary, and Tertiary. We have (§ 1)—

$$u_2 = \frac{dw_1}{dy} - \frac{dv_1}{dz}, v_2 = \frac{du_1}{dz} - \frac{dw_1}{dx}, w_2 = \frac{dv_1}{dx} - \frac{du_1}{dy} \quad . \quad . \quad . \quad (1)$$

$$u_3 = \frac{dw_2}{dy} - \frac{dv_2}{dz}, v_3 = \frac{du_2}{dz} - \frac{dw_2}{dx}, w_3 = \frac{dv_2}{dx} - \frac{du_2}{dy} \quad . \quad . \quad . \quad (2)$$

Eliminating u_2, v_2, w_2 from (2) by (1), we find—

$$u_3 = \frac{d}{dx} \left(\frac{du_1}{dx} + \frac{dv_1}{dy} + \frac{dw_1}{dz} \right) - \left(\frac{d^2 u_1}{dx^2} + \frac{d^2 u_1}{dy^2} + \frac{d^2 u_1}{dz^2} \right); \text{ \&c. } \quad . \quad . \quad . \quad (3)$$

But by our assumption (§ 2) of incompressibility in the Primary—

$$\frac{du_1}{dx} + \frac{dv_1}{dy} + \frac{dw_1}{dz} = 0 \quad . \quad . \quad . \quad . \quad (4)$$

Hence (3) becomes—

$$u_3 = -\nabla^2 u_1, \quad v_3 = -\nabla^2 v_1, \quad w_3 = -\nabla^2 w_1 \quad . \quad . \quad . \quad (5)$$

¹ From Poisson's well-known elementary theorem $\nabla^2 V = -4\pi\rho$.

² *Electrostatics and Magnetism*, § 517 (postscript) (c).

³ *Electricity and Magnetism*, § 604.

where, as in Article xxvii. (November 1846) of my Collected Mathematical and Physical Papers (vol. i.)—

$$\nabla^2 = \frac{d^2}{dx^2} + \frac{d^2}{dy^2} + \frac{d^2}{dz^2} \quad . \quad . \quad . \quad . \quad . \quad . \quad (6)^1$$

This (5) is the promised proof of § 3.

6. Let now u, v, w denote the components of electric current at (x, y, z) in the electric system of § 4; so that—

$$4\pi u = u_3 = -\nabla^2 u_1; \quad 4\pi v = v_3 = -\nabla^2 v_1; \quad 4\pi w = w_3 = -\nabla^2 w_1 \quad . \quad . \quad (7)$$

which, in virtue of (4), give—

$$\frac{du}{dx} + \frac{dv}{dy} + \frac{dw}{dz} = 0 \quad . \quad . \quad . \quad . \quad . \quad (8)$$

Hence the components of electro-motive force due to change of current being (§ 5)—

$$-\frac{du_3}{dt}, \quad -\frac{dv_3}{dt}, \quad -\frac{dw_3}{dt},$$

are equal to—

$$4\pi \nabla^{-2} \frac{du}{dt}, \quad 4\pi \nabla^{-2} \frac{dv}{dt}, \quad 4\pi \nabla^{-2} \frac{dw}{dt} \quad . \quad . \quad . \quad . \quad (9)$$

and therefore if Ψ denote electrostatic potential, we have, for the equations of the electric motion (§ 5)—

$$u = \frac{1}{\kappa} \left(\nabla^{-2} \frac{du}{dt} - \frac{d\Psi}{dx} \right); \quad v = \frac{1}{\kappa} \left(\nabla^{-2} \frac{dv}{dt} - \frac{d\Psi}{dy} \right); \quad w = \frac{1}{\kappa} \left(\nabla^{-2} \frac{dw}{dt} - \frac{d\Psi}{dz} \right). \quad (10)$$

where κ denotes $\frac{1}{4\pi}$ of the specific resistance.

7. As Ψ is independent of t , according to § 4, we may, conveniently for a moment, put—

$$u + \frac{d\Psi}{\kappa dx} = \alpha; \quad v + \frac{d\Psi}{\kappa dy} = \beta; \quad w + \frac{d\Psi}{\kappa dz} = \gamma \quad . \quad . \quad . \quad . \quad (11)$$

and so find, as equivalents to (10)—

$$\frac{d\alpha}{dt} = \nabla^2 (\kappa \alpha); \quad \frac{d\beta}{dt} = \nabla^2 (\kappa \beta); \quad \frac{d\gamma}{dt} = \nabla^2 (\kappa \gamma) \quad . \quad . \quad . \quad (12)$$

The interpretation of this elimination of Ψ may be illustrated by considering, for example, a finite portion of *homogeneous* solid conductor, of any shape (a long thin wire with two ends, or a short thick wire, or a solid globe, or a lump, of any shape, of copper or other metal homogeneous throughout), with a constant flow of electricity maintained through it by electrodes from a voltaic battery or other source of electric energy, and with proper appliances over its whole boundary, so regulated as to keep any given constant potential at every point of the boundary; while currents are caused to circulate through the interior by varying currents in circuits exterior to it. There being no *changing electrification* by our supposition of § 4, Ψ can have no contribution from electrification within our conductor; and therefore throughout our field—

$$\nabla^2 \Psi = 0 \quad . \quad . \quad . \quad . \quad . \quad . \quad (13)$$

which, with (8) and (11), gives—

$$\frac{d\alpha}{dx} + \frac{d\beta}{dy} + \frac{d\gamma}{dz} = 0 \quad . \quad . \quad . \quad . \quad . \quad (14)$$

Between (12) and (14) we have four equations for three unknown quantities. These *in the case of homogeneousness* (κ constant) are equivalent to only three, because in this case (14) follows from (12) provided (14) is satisfied initially, and the proper surface condition is maintained to prevent any violation of it from supervening.

¹ Maxwell, for quaternionic reasons, takes ∇^2 the negative of mine.

But unless κ is constant throughout our field, the four equations (12) and (14) are mutually inconsistent; from which it follows that our supposition of unchangingness of electrification (§ 4) is not generally true. An interesting and important practical conclusion is, that when currents are induced in any way, in a solid composed of parts having different electric conductivities (pieces of copper and lead, for example, fixed together in metallic contact), there must in general be changing electrification over every interface between these parts. This conclusion was not at first obvious to me; but it ought to be so by anyone approaching the subject with mind undisturbed by mathematical formulas.

8. Being thus warned off heterogeneousness until we come to consider changing electrification and incomplete circuits, let us apply (10) to an infinite homogeneous solid. As (8) holds through all space according to our supposition in § 4, and as κ is constant, (13) must now hold through all space, and therefore $\Psi = 0$, which reduces (10) to—

$$u = \frac{1}{\kappa} \nabla^{-2} \frac{du}{dt}; \quad v = \frac{1}{\kappa} \Delta^{-2} \frac{dv}{dt}; \quad w = \frac{1}{\kappa} \nabla^{-2} \frac{dw}{dt} \quad . \quad . \quad (15)$$

These equations express simply the known law of *electro-magnetic* induction. Maxwell's equations (7) of § 783 of his 'Electricity and Magnetism,' become in this case—

$$\mu \left(4\pi C + K \frac{d}{dt} \right) \frac{du}{dt} = \nabla^2 u, \text{ \&c.} \quad . \quad . \quad . \quad (15')$$

which cannot be right, I think, according to any conceivable hypothesis regarding electric conductivity, whether of metals, or stones, or gums, or resins, or wax, or shellac, or india-rubber, or gutta-percha, or glasses, or solid or liquid electrolytes; being, as seems to me, vitiated for complete circuits by the curious and ingenious, but as seems to me not wholly tenable hypothesis which he introduces, in § 610, for incomplete circuits.

9. The hypothesis which I suggest for incomplete circuits, and consequently varying electrification, is simply that the components of the electro-motive force due to electro-magnetic induction are still $4\pi \nabla^{-2} du/dt$, &c. Thus, for the equations of motion, we have simply to keep equations (10) unchanged, while not imposing (8), but instead of it taking

$$'v',^2 \left(\frac{du}{dx} + \frac{dv}{dy} + \frac{dw}{dz} \right) = \frac{d}{dt} \nabla^2 \Psi = -\rho \quad . \quad . \quad . \quad (16)$$

where ρ denotes 4π times the electric density at time t , and place (x, y, z) , and ' v ' denotes the number of electrostatic units in the electro-magnetic unit of electric quantity. This equation expresses that the electrification of which Ψ is the potential, diminishes and increases in any place according as electricity flows more out than in or more in than out. We thus have four equations, (10) and (16), for our four unknowns, u, v, w, Ψ ; and I find simple and natural solutions, with nothing vague or difficult to understand, or to believe when understood, by their application to practical problems, or to conceivable ideal problems, such as the transmission of ordinary or telephonic signals along submarine telegraph conductors and land lines, electric oscillations in a finite insulated conductor of any form, transference of electricity through an infinite solid, &c. &c. This, however, does not prove my hypothesis. Experiment is required for informing us as to the real electro-magnetic effects of incomplete circuits; and, as Helmholtz has remarked, it is not easy to imagine any kind of experiment which could decide between different hypotheses which may occur to anyone trying to evolve out of his inner consciousness a theory of the mutual force and induction between incomplete circuits.

6. On the Transference of Electricity within a Homogeneous Solid Conductor. By Professor Sir WILLIAM THOMSON, LL.D., F.R.S.

Adopting the notation and formulas of my previous paper, and taking ρ to denote 4π times the electric density at time t , and place (x, y, z) , we have—

$$-\rho = \nabla^2 \Psi = 'v'^2 \int \left(\frac{du}{dx} + \frac{dv}{dy} + \frac{dw}{dz} \right) dt \quad . \quad . \quad . \quad (17)$$

and, eliminating u, v, w, Ψ by this from (10), we find, on the assumption of κ constant,

$$\kappa \frac{d}{dt} \nabla^2 \rho = \frac{d^2 \rho}{dt^2} - 'v'^2 \nabla^2 \rho \quad . \quad . \quad . \quad (18)$$

The settlement of boundary conditions, when a finite piece of solid conductor is the subject, involves consideration of u, v, w , and for it, therefore, equations (17) and (12) must be taken into account; but when the subject is an infinite homogeneous solid, which, for simplicity, we now suppose it to be, (18) suffices. It is interesting and helpful to remark that this agrees with the equation for the density of a viscous elastic fluid, found from Stokes's equations for sound in air with viscosity taken into account; and that the values of u, v, w , given by (17) and (10), when ρ has been determined, agree with the velocity components of the elastic fluid if the simple and natural enough supposition be made that viscous resistance acts only against change of shape, and not against change of volume without change of shape.

For a type-solution assume—

$$\rho = A E^{-\kappa t} \cos \frac{2\pi x}{a} \cos \frac{2\pi y}{b} \cos \frac{2\pi z}{c} \quad . \quad . \quad . \quad (19)$$

and we find, by substitution in (18)—

$$q^2 - \frac{\kappa}{L^2} q + \frac{'v'^2}{L^2} = 0 \quad . \quad . \quad . \quad (20)$$

where—

$$L^2 = 1 / 4\pi^2 \left(\frac{1}{a^2} + \frac{1}{b^2} + \frac{1}{c^2} \right) \quad . \quad . \quad . \quad (21)$$

Hence, by solution of the quadratic (20) for q —

$$q = \frac{1}{2} \frac{\kappa}{L^2} \left\{ 1 \pm \sqrt{1 - \frac{4 'v'^2 L^2}{\kappa^2}} \right\} \quad . \quad . \quad . \quad (22)$$

[In the communication to the Section numerical illustrations of non-oscillatory and of oscillatory discharge were given.]

7. *Five Applications of Fourier's Law of Diffusion, illustrated by a Diagram of Curves with Absolute Numerical Values.* By Professor Sir WILLIAM THOMSON, LL.D., F.R.S.

1. Motion of a viscous fluid.
2. Closed electric currents within a homogeneous conductor.¹
3. Heat.
4. Substances in solution.

¹ This subject is essentially the 'electro-magnetic induction' of Henry and Faraday. It is essentially different from the 'diffusion of electricity' through a solid investigated by Ohm in his celebrated paper 'Die Galvanische Kette mathematisch bearbeitet,' Berlin, 1827; translated in Taylor's 'Scientific Memoirs,' vol. ii. part viii., 'The Galvanic Circuit investigated Mathematically,' by Dr. G. S. Ohm. In Ohm's work electro-magnetic induction is not taken into account, nor does any idea of an electric analogue to inertia appear. The electro-motive force considered is simply that due to the difference of electrostatic potential in different parts of the circuit, unsatisfactorily, and even not accurately, explained by what, speaking in his pre-Greenian time, he called 'the eletroscopic force of the body,' and defined or explained as 'the force with which the electroscope is repelled or attracted by the body;' the electroscope being 'a second movable body of invariable electric condition.'

5. Electric potential in the conductor of a submarine cable.

1. Fourier's now well-known analysis of what he calls the 'linear motion of heat' is applicable to every case of diffusion in which the substance concerned is in the same condition at all points of any one plane parallel to a given plane. The differential equation of diffusion,² for the case of constant diffusivity κ , is—

$$\frac{dv}{dt} = \kappa \frac{d^2v}{dx^2},$$

where v denotes the 'quality' at time t and at distance x from a fixed plane of reference. This equation stated in words is as follows:—Rate of augmentation of the 'quality' per unit of time is equal to the diffusivity multiplied into the rate of augmentation per unit of space of the 'quality.'

The meaning of the word 'quality' here depends on the subject of the diffusion, which may be any one of the five cases referred to in the title above.

2. If the subject is motion of a viscous fluid, the 'quality' is any one of three components of the velocity, relative to rectangular rectilinear co-ordinates. But in order that Fourier's diffusional law may be applicable we must either have the motion very slow, according to the special definition of slowness in Article xcvi. below; or the motion must be such that the velocity is the same for all points in the same stream-line, and would continue to be steadily so if viscosity were annulled at any instant. This condition is satisfied in laminar flow, and more generally in every case in which the stream-lines are parallel straight lines. It is also satisfied in the still more general case of stream-lines, coaxal circles with velocity the same at all points at the same distance from the axis. Our present illustration, however, is confined to the case of laminar flow, to which Fourier's diffusional laws for what he calls 'linear motion' (as explained above in § 1) is obviously applicable without any limitation to the greatness of the velocity in any part of the fluid considered (though with conceivably a reservation in respect to the question of stability³). In this case the 'quality' is simply fluid velocity.

3. If the subject is electric current in a non-magnetic metal, with stream-lines parallel straight lines, the 'quality' is simply current-density, that is to say, strength of current per unit of area perpendicular to the current. The perfect mathematical⁴ analogy between the electric motion thus defined, and the corresponding motion of a viscous fluid defined in § 2 was accentuated by Mr. Oliver Heaviside in the 'Electrician,' July 12, 1884; and in the following words in the 'Philosophical Magazine' for 1886, second half-year, p. 135: 'Water in a round pipe is started from rest and set into a state of steady motion by the sudden and continued application of a steady longitudinal dragging or shearing force applied to its boundary. This analogue is useful because everyone is familiar with the setting of water in motion by friction on its boundary, transmitted inward by viscosity.' Mr. Heaviside well calls this analogue 'useful.' It is, indeed, a very valuable analogy, not merely in respect to philosophical consideration of electricity, ether, and ponderable matter, but as facilitating many important estimates, particularly some relating to telephonic conductors and conductors for electric lighting on the 'alternate-current' system. In a short article to be included in volume iii. of my collected papers, which I hope will soon be published, I intend to describe a generalisation, with, as will be seen, a consequently essential modification of this analogy, by which it is extended to include the mutual induction between conductors separated by air or other

¹ This subject belongs to the Ohmian electric diffusion pure and simple, worked out by aid of Green's theory of the capacity of a Leyden jar (see 'Mathematical and Physical Papers,' vol. ii., art. lxxiii.).

² See 'Mathematical and Physical Papers,' vol. ii., art. lxxii.

³ See 'Stability of Fluid Motion,' § 28 *Philosophical Magazine*, August 1887.

⁴ It is essentially a mathematical analogy only; in the same sense as the relation between the 'uniform motion of heat' and the mathematical theory of electricity, which I gave in the *Cambridge Mathematical Journal* forty-six years ago, and which now constitutes the first article of my 'Electrostatics and Magnetism,' is a merely mathematical analogy.

insulators, and currents in solids of different conductivity fixed together in contact.

4. If the subject is heat, as in Fourier's original development of the theory of diffusion, the '*quality*' is temperature.

5. If the subject is diffusion of matter, the '*quality*' is density of the matter diffused, or deviation of density from some mean or standard density considered. It is to Fick, thirty-three years ago demonstrator of anatomy, and now professor of physiology in the University of Zurich, that we owe this application of Fourier's diffusional theory, so vitally important in physiological chemistry and physics, and so valuable in natural philosophy generally. When the substance through which the diffusion takes place is fluid, a very complicated but practically important subject is presented if the fluid be stirred. The exceedingly rapid progress of the diffusion produced by vigorous up-and-down stirring, causing to be done in half a minute the diffusional work which would require years or centuries if the fluid were quiescent, is easily explained; and the explanation is illustrated by the diagram of curves, § 7 below, with the time-values given for sugar and common salt. Look at curve No. 1, and think of the corresponding curve with vertical ordinates diminished in the ratio of 1 to 40. The corresponding diffusion would take place for sugar in 11 seconds, and for salt in $3\frac{1}{2}$ seconds. The case so represented would quite correspond to a streaky distribution of brine and water or of syrup and water, in which portions of greatest and least salinity or saccharinity are within half a millimetre of one another. This is just the condition which we see, in virtue of the difference of optic refractivity produced by difference of salinity or of saccharinity, when we stir a tumbler of water with a quantity of undissolved sugar or salt on its bottom. If water be poured very gently on a quantity of sugar or salt in the bottom of a tumbler with violent stirring up guarded against by a spoon, the now almost extinct Scottish species called '*toddy ladle*' being the best form, or better still a little wooden disc which will float up with the water; and if the tumbler be left to itself undisturbed for two or three weeks, the condition at the end of 17×10^5 seconds (20 days) for the case of sugar, or 5.4×10^5 seconds (6 days) for salt, will be that represented by No. 10 curve in the diagram.

6. If the subject be electricity in a submarine cable, the '*quality*' is electric potential at any point of the insulated conductor. It is only if the cable were a straight line that x would be (as defined above) distance from a fixed plane: but the cable need not be laid along a straight line; and the proper definition of x for the application of Fourier's formula to a submarine cable is the distance along the cable from any point of reference (one end of the cable, for example) to any point of the cable. For this case the diffusivity is equal to the conductivity of its conductor, reckoned in electrostatic units, divided by the electrostatic capacity of the conductor per unit length insulated as it is in gutta-percha, with its outer surface wet with sea water, which, in the circumstances, is to be regarded as a perfect conductor. For demonstration of this proposition see vol. ii., art. lxxiii. (1855) of my collected papers.

7. EXPLANATION OF DIAGRAM SHOWING PROGRESS OF LAMINAR DIFFUSION.

In each curve—

$$\frac{1}{10} NP = \frac{2}{\sqrt{\pi}} \int_0^{2x/i} dq \cdot e^{-q^2},$$

where x denotes the number of centimetres in ON , and i the '*curve-number*.' The curves are drawn directly from the values of the integral given in Table III. appended to De Morgan's article '*On the Theory of Probabilities*,' '*Encyclopædia Metropolitana*,' vol. ii. pp. 483–84.

NP denotes the '*quality*' (defined below)

{ at distance = ON from initial surface or interface,
and at time equal in seconds to [*'curve-number'*]² divided by sixteen times the diffusivity in square centimetres per second.

Subject of Diffusion	'Quality' represented by $\frac{1}{10} NP$
Motion of a viscous fluid	Ratio of the velocity at <i>N</i> to the constant velocity at <i>O</i>
Closed electric currents within a homogeneous conductor	Current-density
Heat	Ratio of temperature <i>minus</i> mean temperature to mean temperature
Substance in solution	Ratio of density <i>minus</i> mean density to mean density
Electric potential in the conductor of a submarine cable	Ratio of potential at <i>N</i> to constant potential at end <i>O</i>

EXAMPLES.

'Curve-number'	Time in seconds	Case of Diffusion
1	27056	Zinc sulphate through water.
1	25720	Copper sulphate through water.
1	17000	Sugar through wood.
1	5400	Common salt through water.
5	1180	Heat through wood.
5	118	Laminar motion of water at 10° Cent.
5	30	Laminar motion of air.
5	7.1	Heat through iron.
5	1.31	Heat through copper.
		Electric current in a homogeneous non-magnetic conductor:
10	.0488	Copper,
10	.0040	Lead,
10	.0038	German silver,
10	.0023	Platinoid.
1,000,000,000	2.15	Electric potential in the Direct U.S. Atlantic Cable.

8. *On Flux and Reflux of Water in Open Channels or in Pipes or other Ducts.*
By Professor JAMES THOMSON, LL.D., F.R.S.

In the autumn of 1872 I was staying at a place named Castlerock, on the north coast of Ireland, between the mouth of the Bann river and the entrance to Lough Foyle. There was an extensive sandy beach there, lashed by the great waves of the Atlantic Ocean. At a part of that beach a small river or stream flowed to the sea; but the sandy beach had been thrown up as a bank, at about high-tide level, obstructing what might have been the direct outfall course for the stream into the sea, and causing the stream to turn to its right and to flow eastward for some distance along the back of that sandy bank before finding an opening for flow out to the sea. Thus, at the back of the bank, a little estuary was formed, along which, when the tide was down, the stream would have for a considerable length a nearly level bed, and into which, when the tide was up, the sea-water entered so as to fill it up to various depths according to the height of the sea-surface.

I happened to be watching with interest the motions of the water in this little

estuary at a time when a considerable depth of water (such as a few feet depth along its mid-channel) was maintained in it by the height of the sea-water outside, and when the slow rising and sinking of the ocean-waves was producing in the estuary a flux and reflux on a small scale like that of the tidal flow in large estuaries.¹ The motions of the water being indicated by numerous little pieces of sea-weed carried in suspension, I noticed that the water at or very close to the channel-bed reversed its landward or seaward flow always much earlier than did the main body of the water in the channel, less affected by contiguity to the bed. The phenomenon being noticed, the reason at once became apparent. The lamina contiguous to the bed, or channel-face, would be always hindered, by the frictional resistance of that face, from getting into so great a velocity, either seaward or landward, as that which would be attained to by the main body of the water. Then, when the water at the sea-end of the estuary was raised in level, by the arrival of an ocean-wave, so as to give a gravitational propulsive influence tending to cause the water to flow landward along the estuary, the main body of the water, in virtue of its inertia with seaward momentum, would continue to flow for some time seaward, flowing as it were uphill;² while the frictionally restrained lamina at the channel-face, being nearly devoid of inertial tendency seaward, would readily yield to the landward gravitational propulsive influence due to the landward surface declivity of the water in the estuary.

Exactly a like explanation, *mutatis mutandis*, is applicable to the case of reversal of the flow from having been landward to its becoming seaward. The channel-face lamina makes its reversal of flow, just as in the other case, *earlier* than does the main body of the water, and for like reason.

It may now further be noticed that precisely corresponding phenomena would present themselves in the flux and reflux of water in a pipe, if, for instance, the pipe were connecting two cisterns, and a plunger were kept oscillating upwards and downwards in one of them so as to cause the alternating flow through the pipe. The phenomena might be very interestingly manifested in an open trough connecting two cisterns, arrangements being made, by a plunger or otherwise, for causing flux and reflux along the trough, and the motions of the water being indicated by small visible particles in suspension in the water or by the dropping in of granules of aniline dye.

It may now be worthy of remark that the hydraulic principle brought into notice in the present paper, in respect to flux and reflux along channels, is closely allied to, and is in some respects identical with, the leading principle set forth in previous papers by myself on the flow of water round bends in rivers, &c. In that case the frictionally resisted and retarded lamina in contiguity with the channel-face, or bed, flows transversely (or rather obliquely) across the channel towards the inner bank of the bend, impelled inwards by gravitational propulsive influence (that is, downhill as it were), while the main body of the stream, flowing quicker in the bend, exerts centrifugal force outwards, or tends inertially out towards the outer bank. The papers here referred to on Flow of Water round Bends in Rivers, &c., are to be found in the 'Proceedings of the Royal Society' for May 1876; in the British Association Report for the Glasgow Meeting, 1876, Section A, page 31 of Transactions of the Sections; in the 'Proceedings of the Royal Society,' 1877, No. 182, page 356; and in the 'Proceedings of the Institution of Mechanical Engineers,' August 1879, p. 456. Also some other important cases in which like principles of fluid motion come into play (in Whirlwinds &c.) are adduced in a paper by myself in the British Association Report for the Montreal Meeting, 1884, Section A, p. 641.

¹ The period of these oscillations may be about from ten to twenty seconds, as I have been informed that Professor Stokes has found, by observations on that coast, that the period from one wave to the next, in the large Atlantic waves there, is at most about seventeen seconds.

² Or, in more precise terms, flowing from a place of lower to a place of higher free-level.

SATURDAY, SEPTEMBER 8.

The following Papers and Report were read :—

DEPARTMENT FOR LIGHT AND ELECTRICITY.

1. *Sur l'application de l'analyse spectrale à la mécanique moléculaire et sur les spectres de l'oxygène.* By Dr. J. JANSSEN.—See Reports, p. 547.
-
2. *On the Absorption Spectrum of Oxygen.*¹ By Professors LIVEING, F.R.S., and DEWAR, F.R.S.

The authors describe the absorption spectrum given by oxygen at various pressures up to 165 atmospheres in a tube, fitted with quartz ends, 1·6 metre long, and at pressures from one to ninety atmospheres in a tube 18 metres long. They confirm generally the results of Egoroff and Janssen, and add some new facts with regard to the absorptions in the more refrangible part of the spectrum.

Of all the absorptions Fraunhofer's A required the least amount of oxygen to produce it in sufficient intensity to be seen, and B came next. All the other absorptions in the visible region seem to be represented, but with less intensity, amongst the telluric bands of the solar spectrum. Neither carbonic acid gas nor nitrous oxide gave any visible absorption. A could not be resolved into lines, because the expansion of the lines with increased density of the oxygen obliterated the interspaces. The rapid increase in the strength of the bands with increasing pressure of the gas accords with Janssen's law that the intensity of the unresolvable absorptions varies as the square of the density of the gas.

With the shorter tube at high pressures the authors found that the absorption of ultra-violet rays beyond λ 2665 was complete, while with the longer column the complete absorption extended much lower, to about λ 3360.

Remarkable effects were observed to arise from variations of density in the gas, the tube becoming quite opaque through internal reflexions when it was heated at one or two points or when gas at high pressure was entering the tube rapidly.

3. *The Spectra of Meteorites compared with the Solar Spectrum.*
By J. NORMAN LOCKYER, F.R.S.
-

4. *On the Harmonic Series of Lines in the Spectra of the Elements.*
By Professor CARL RUNGE.

Similar to the formula found by Mr. Balmer, of Zurich,² in 1885 for the wave-lengths of thirteen lines of the hydrogen spectrum there exist, as Professor Kayser and I have found, formulas for the groups of lines of other elements, which Professors Liveing and Dewar have called 'harmonic series of lines,' and which they have compared to the series of overtones emitted by a vibrating elastic body.

The formulas have the form

$$\text{wave-length} = \frac{1}{a + bn^{-1} + cn^{-2}},$$

$$\text{or wave-length} = \frac{1}{a + bn^{-2} + cn^{-4}},$$

where a , b , c are constants and n assumes consecutive values of the series of entire numbers. I give an example of a series of eight lines in the spectrum of lithium observed by Liveing and Dewar :—

¹ For full details see *Phil. Mag.* Sept. 1888, and *Chem. News*, vol. lviii. p. 163.

² *Wiedemann's Annalen*, 25, pp. 80–87.

Wave-length = $\frac{1}{4341.4 + 186.5n^{-1} - 11635n^{-2}}$ millimeter				
n	Wave-lengths		Difference	Remarks
	Calculated	Observed		
3	3232.0	3232.0	0.0	The wave-lengths are given in Angström's units; that is, 10 ⁻⁷ millimeters.
4	2741.0	2741.0	0.0	
5	2562.0	2561.5	-0.5	
6	2474.7	2475.0	+0.3	
7	2425.2	2425.5	+0.3	
8	2394.3	2394.5	+0.2	
9	2373.7	2373.5	-0.2	
10	2359.2	2359.0	-0.2	

Liveing and Dewar give 0.3 Angström's units as their probable error. According to that the formula might be absolutely correct. However, our other formulas do not agree quite so well with the observations. They contain series of lines in the spectra of thallium, potassium, sodium, tin, zinc, and magnesium. As the spectrum defines an element, so the constants of the formula may be said to define the element. Possibly they will be found to be in some connection with the atomic weight.

5. *A Vortex Analogue of Static Electricity.*
By Professor W. M. HICKS, M.A., F.R.S.

Consider two bodies in contact placed in an infinite fluid, and with a vortex filament the ends of which are one on one surface, the other on the other. If now the surfaces be separated from one another, there will be formed at the point where they separate a hollow vortex filament stretching from one to the other, with rotation equal and opposite to that of the original filament. As the bodies are moved apart these filaments will not in general take up a position of rest. If the strength of the original filament be very great, or if there be several of them, the resulting hollow vortex will, through instability, split up into a number of smaller ones.

If the resulting number be very large they will ultimately take up some position of stable equilibrium. What the distribution in this case will be I cannot say, but the following is one state of equilibrium and probably, although I have not proved it, a stable one. The two sets of filaments will be mixed up with each other, and each will distribute itself according to the same law as the distribution of lines of force between the two bodies supposed equally and oppositely electrified.

In the case of the original filaments, as the surfaces are further and further separated, their sections become smaller and smaller. This is, however, not the case with the hollow filaments. Their section depends only on the pressure of the fluid and their circulation, and as these remain constant the areas of their section also remain so. In such a hollow vortex the pressure inside sinks to zero. Consequently the portion of the surface on which it abuts experiences a diminution of pressure, a diminution which is the same at all distances. The two bodies are therefore attracted. Moreover, as the two bodies separate further, the distribution of the filaments being the same as that of electrical lines of force, and the diminution of pressure for each line being constant, it follows that the force between the two bodies follows precisely the same laws as the force between the two bodies supposed equally and oppositely electrified. It can be shown that the effect of the original filaments is similar, the diminution of pressure being half as large again as for the hollow vortices.

If another surface be brought into the presence of the others, some of the

filaments would abut on this. These would break off, and rearrange themselves so that some of the filaments would end on it and an equal number start from it.

Call those ends of the filaments positive at which the rotation, looked at *from* the surface on which they abut, is right-handed; and those ends negative at which the rotation is left-handed. The two ends of any filament will then always be of opposite name.

The analogy with electrical action is then close. Two bodies, A B, brought in contact touch in innumerable points, owing possibly to the different states of motion of the ether at their surfaces; a state of equilibrium is set up, consisting of a kind of sifting of vortex motion already subsisting, so that on the whole more lines go from A to B than *vice versa*. This is *E.M.F. of contact*. Separate the bodies; one has a number of positive ends of hollow filaments, and the other an equal number of negative ends. *The bodies are equally and oppositely electrified*. The forces in the hydrodynamical case and in its electrical analogue follow the same laws.

Bring into the field another surface C; the filaments rearrange themselves as mentioned above, the negative and positive ends abutting on C being equal. *This is induced electricity*.

If the surface C consist of a large number of small unconnected surfaces, the filaments will arrange themselves in some manner depending on the sizes and distances of the unconnected parts, the field will be disturbed in a similar way to that in an electric field into which a different dielectric is placed. This is the analogue of a non-uniform specific inductive capacity. So far the ground is pretty safe. The succeeding remarks must be regarded as speculative.

Return to the case of the two separated surfaces A and B; what will happen if they be connected by a third surface—say, to fix our ideas—a long, narrow cylinder or wire? It is not so easy to say certainly what the exact rearrangement will be. It would seem very probable that the hollow filaments near the wire would at once be replaced by circulation round the wire. In this case the solid filaments must rotate as a whole round it, while at the same time, although this has not been proved, they will contract, their ends move along until they come together, form a ring and get mixed up in the surrounding fluid. This would correspond to the *current of discharge*. But notice that if this is so the fluid outside the wire rotates round the wire while a stationary state is being reached, and, as we know that the field round a current is a magnetic field, it follows that the *analogue of a magnetic field is a flow along the magnetic lines of force*.

It may, however, be further necessary that these streams must contain vortex filaments moving with the fluid, their axes at every point being perpendicular to the lines of force there.

If the field is determined by the flow of fluid independently of the vortex motion it is not easy to see the hydrodynamical analogue of the induction of currents when, say, a wire moves across a uniform magnetic field. If, however, the vortex filaments as above are a necessary adjunct, it is conceivable how a movement of the wire across the lines of flow and amongst the filaments produce an instantaneous disarrangement which will travel through the vortical fluid with the velocity of propagation of transverse vibrations in a vortical fluid. That is in the ether as Sir W. Thomson has shown with the velocity of light.

It is difficult to see any analogue to the rotation of the plane of polarisation of light by a magnetic field.

6. *On a Diffusion Photometer.* By J. JOLY, M.A., B.E.

This photometer in its original form was brought before the British Association in 1885 by Professor Fitzgerald for the author. The improved form, made of translucent glass, is now shown. A full account will be found in the 'Philosophical Magazine,' July 1886, p. 26.

7. *Third Report of the Committee on Electrolysis.*—See Reports, p. 339.

DEPARTMENT FOR MATHEMATICS AND GENERAL PHYSICS.

1. On Centres of Finite Twist and Stretch.

By Professor R. W. GENESE, M.A.

Given two directly similar figures $ABC\dots$, $A'B'C'\dots$ in a plane; it is known that one may be transformed into the other by a twist about a certain point I , and a proper stretch from that point. But it will be seen that the transformation may be effected by an equal twist about any point O in the plane (so as to bring AB parallel to $A'B'$) followed by a stretch from a different centre S , or equally well by a stretch from S followed by a twist round a proper point O' not coincident with O . It would seem worth while to consider the relations between the centres.

FIG. 1.

Let I be brought to J by the twist ω round O ; then it must be brought back by the stretch from S . Thus it is clear that *for a given twist and stretch the triangle OIS is of constant species.*

Similarly if I be brought by the stretch first to J' it must be brought back by the rotation about O' .

It is at once seen that (1) S, O, O' are collinear, (2) SO' is the stretched position of SO , (3) IO, IO' are equally inclined to SI and are to each other as $SO : SO'$, so that O' is the position of O after the first twist and stretch.

If we start again with two symmetrically similar figures, one may be transformed into the other by a half turn about *any* axis in the plane, together with a twist and stretch from the proper centre, and the relation between the axis and the centre might be worth investigation. For the present paper, however, it suffices to observe that by taking an axis parallel to the bisector of the angle between two corresponding sides the twist may be avoided; it is not difficult to show that the locus of the stretch-centres for axes parallel to this axis is a straight line at right angles to it. In the case in which the stretch-centre is on the half-turn axis, the locus and axis form two remarkable straight lines which should bear the name of the illustrious mathematician Bellavitis who first noticed them.

Their existence may be briefly demonstrated, thus:

Let $AB = p$, $A'B' = p'$ be corresponding sides, and let AA', BB' be divided at L, M so that $AL : LA' = p : p' = BM : MB'$. Then LM shall be equally inclined to p, p' .

FIG. 2.

Complete the parallelograms $BALC$, $B'A'LC'$. Then, since $BC : B'C' = p : p' = BM : MB'$, CC' passes through M ; and $CM : MO' = p : p' = LC : L'O'$; therefore LM is equally inclined to LC , LC' .

A similar demonstration holds if L_1, M_1 be the points dividing AA' , BB' externally in the ratio $p : p'$. The lines LM , L_1M_1 intersecting at right angles at S (see fig. 3), and $\{A'LAL_1\}$ being harmonic, we see that SL bisects the angle ASA' and similarly BSB' . And $SA : SA' = AL : LA' = p : p'$. Thus AB may be transformed into $A'B'$ by a half-turn round LM with a stretch from S .

Again, AB may be otherwise transformed into $A'B'$, thus: let the circum-circles EAA' , EBB' (E being the intersection of AB , $A'B'$) meet in I ; then IAB , $IA'B'$ are directly similar and a twist round and stretch from I suffices. From this property I , as well as S , lies on the circles described on LL_1 , MM_1 as diameters.

Now let ML meet AB in O $A'B'$ in O' . Then AB may be changed into $A'B'$ by a twist round O followed by a stretch from S , or by a stretch from S followed by a twist round O' , the twist in all cases being the angle $AEA' = \omega$. Hence, angle $OIO' = \omega$, and E, O, I, O' are concyclic; hence, EI bisects angle OIO' , and, from previous reasoning IS bisects the same angle externally; therefore EIS is a right angle.

Again, let L_1M_1 meet AB , $A'B'$ at Q, Q' . Then Q comes to Q' on the half-turn and stretch. Whence $QIQ' = \omega$, and E, Q', Q, I are concyclic. Also $QIS = \frac{1}{2}QIQ' = \frac{1}{2}\omega = QOS$. Therefore I lies on the circle OSQ , i.e., on OQ as diameter; and similarly on the circle $O'SQ'$.

FIG. 3.

A particular case is worthy of notice. If A, B, B', A' be concyclic the point S coincides with the intersection of AB' , $A'B$, and it is then also the centre for the transformation of AA' into BB' . Then the angle SIF is a right angle, and I is the foot of the perpendicular from S on EF .

2. On Recurring Decimals and Fermat's Theorem.

By PROFESSOR R. W. GENESE, M.A.

Let θ_r denote the number formed of r digits, each being θ ; and let θ_m be the smallest such number exactly divisible by a given prime number $p > 5$. Then $\frac{1}{p}$

gives rise to m recurring decimals, and any proper fraction with p for denominator must give the same number of decimals. For if, say, $\frac{a}{p}$ gave fewer places, it could be converted into a fraction with denominator of form 9_r , r being less than m , in which case p would divide 9_r , contrary to the hypothesis above.

Now in the conversion of $\frac{a}{p}$ into m recurring decimals there are m different remainders, say $b, c, d \dots a$; then the m fractions $\frac{b}{p}, \frac{c}{p}, \&c.$, give rise to the same cycle of digits. Thus the fractions $\frac{1}{p}, \frac{2}{p}, \frac{3}{p}, \&c., \frac{p-1}{p}$ must be capable of arrangement in groups, m at a time, giving the same cycle:

$$\begin{aligned} \text{i.e. } m \text{ is a factor of } p-1 \\ \therefore 9_m \quad \quad \quad \text{,,} \quad \quad \quad 9_{p-1} \\ \therefore p \quad \quad \quad \text{,,} \quad \quad \quad 9_{p-1} \\ \text{i.e. of } 10^{p-1} - 1. \end{aligned}$$

Repeating the reasoning in a different scale of notation we have Fermat's theorem: the radix must clearly be prime to p , otherwise the fraction $\frac{1}{p}$ would give rise to pure as well as recurring decimals.

In connection with recurring decimals a curious property may be noticed of the equivalent to $\frac{1}{81}$, viz., $\cdot 012345679$ (nine different digits out of the usual ten), the 8 being absent. If we multiply this by a number less than 81, and prime to it, a similar result holds, the absent digit being the defect of the multiplier from the next greater multiple of 9, thus:

$$\begin{aligned} \frac{8}{81} &= \cdot 098765432, 1 \text{ absent} \\ \frac{4}{81} &= \cdot 049382716, 5 \quad \quad \quad \text{,,} \\ \frac{7}{81} &= \cdot 086419753, 2 \quad \quad \quad \text{,,} \\ \frac{28}{81} &= \cdot 345679012, 8 \quad \quad \quad \text{,,} \quad \quad \quad = 4 \times 9 - 28. \end{aligned}$$

Hence a new, so-called, recreation. If the number 012345679 be multiplied by a single digit, and the digits only of the product be given in any order, the multiplier can be detected.

3. On the Relations between Orbits, Catenaries, and Curved Rays.

By Professor J. D. EVERETT, F.R.S.

If the same curve be regarded—

I. As the orbit of a particle under a force of intensity P directed to a fixed point.

II. As the curve assumed by a string under a force of magnitude F per unit length, opposite in direction to P .

III. As the path of a curved ray of light in a medium in which the absolute index of refraction μ is a function of distance from the common centre of the forces P and F .

Then, in passing from point to point of the curve, the ratio of P to F will vary directly as μ .

In fact, from the well-known formulæ

$$vp = h, Tp = C, \mu p = A, P = \frac{h^2}{p^3} \frac{dp}{dr}$$

(in which p denotes the perpendicular from the common centre on the tangent, v the velocity in the orbit, T the tension of the string, and h , C , and A constants), together with the additional formula (proved in my edition of 'Todhunter's Statics').

$$F = \frac{C}{p^2} \frac{dp}{dr},$$

we have

$$\frac{P}{F} \propto \frac{1}{p} \propto v \propto T \propto \mu.$$

If, instead of supposing the three curves identical, we suppose them similar and similarly placed with respect to the centres in question, the above results will obviously remain true.

Further, instead of supposing the forces central, and the index a function of distance from centre, let us make the more general supposition that, at corresponding points of the orbit and the string, the forces P and F are parallel and opposite, and that, at the corresponding point of the curved ray, the direction of most rapid increase of μ is the same as the direction of P ; then we have the following equations, in which ϕ denotes the angle between the direction of F and the tangent drawn in the direction of increasing s .

$$P \cos \phi = - \frac{d}{ds} \frac{v^2}{2} \quad . \quad . \quad . \quad (1) \quad P \sin \phi = \frac{v^2}{\rho} \quad . \quad . \quad . \quad (2)$$

$$F \cos \phi = - \frac{dT}{ds} \quad . \quad . \quad . \quad (3) \quad F \sin \phi = \frac{T}{\rho} \quad . \quad . \quad . \quad (4)$$

$$\frac{d \log \mu}{dr} \cos \phi = \frac{d \log \mu}{ds} \quad . \quad . \quad . \quad (5) \quad - \frac{d \log \mu}{dr} \sin \phi = \frac{1}{\rho} \quad . \quad (6)$$

$$. \quad \text{From (1) and (2), } \cot \phi = - \rho \frac{d \log v}{ds};$$

$$,, \quad (3) \text{ and (4), } \cot \phi = - \rho \frac{d \log T}{ds};$$

$$,, \quad (5) \text{ and (6), } \cot \phi = - \rho \frac{d \log \mu}{ds}.$$

Equating the three values of $\cot \phi$, we have

$$\frac{d \log v}{ds} = \frac{d \log T}{ds} = \frac{d \log \mu}{ds}.$$

Hence the logarithms of v , T and μ change by equal amounts; that is,

$$v \propto T \propto \mu.$$

$$\text{From (2) and (4), } \frac{P}{F} = \frac{v^2}{T}. \quad \text{But } \frac{v}{T} \text{ is constant;}$$

$$\therefore \frac{P}{F} \propto v \propto T \propto \mu.$$

The proportionality of v , T and μ can be proved without the calculus by regarding the three curves as the limit of three similar polygons.

In the first polygon a particle moves along the sides under no forces, but is acted on by impulsive forces at the corners.

The second polygon is a polygon of string kept tight by forces applied at the corners, the lines of action of these applied forces being parallel to the impulses in the first polygon, but opposite to them in direction.

The third polygon is the path of a ray which undergoes refraction at each corner by passing out of one uniform medium into another uniform medium; and

the normals to the surfaces of junction of the media are parallel to the impulses in the first polygon or to the applied forces in the second.

The angles of the three polygons are thus similarly divided by the lines which are drawn one at each angle. Call the two parts into which one of the angles is divided α and α' , one being acute and the other obtuse.

In the first polygon, since the component velocity perpendicular to the impulse remains unchanged, we have

$$v \sin \alpha = v' \sin \alpha',$$

v and v' denoting the velocities before and after an impulse.

In the second polygon, since the applied force at any corner is balanced by the two tensions T, T' of the two portions of string which meet there, we have

$$T \sin \alpha = T' \sin \alpha'.$$

In the third polygon the law of sines in refraction gives

$$\mu \sin \alpha = \mu' \sin \alpha'.$$

Hence we have

$$\frac{v}{v'} = \frac{T}{T'} = \frac{\mu}{\mu'} = \frac{\sin \alpha'}{\sin \alpha}.$$

The changes in v, T , and μ are therefore proportional when we pass from any side to the next.

4. On the Stretching of Liquids.

By Professor A. M. WORTHINGTON, M.A., F.R.A.S.

The author described the three methods that have been employed by previous observers to subject a liquid to tension. These are:—

- (1) *The barometer tube method*, by which Professor Osborne Reynolds had succeeded in subjecting mercury to a tension of five or six atmospheres due to its own weight.
- (2) *The centrifugal method*, devised by the same observer, and by means of which he had subjected water to a pull of about five atmospheres (72.5 lbs. per square inch); while the author had succeeded in reaching with alcohol a tension of 7.9 atmospheres, or 116 lbs. per square inch, and with strong sulphuric acid a tension of 11.8 atmospheres, or 173.4 lbs. per square inch.
- (3) *The method of cooling*, discovered by Berthelot, and described by him, 'Ann. de Chimie' xxx. (1850): Sur la dilatation forcée des liquides.

In this method a liquid deprived of air by boiling nearly fills a very strong closed glass tube. On slight heating it expands and fills the whole tube, compressing the residual air, which dissolves under the increasing pressure and finally disappears. The liquid may now be greatly cooled, but remains extended, filling the whole tube, of which at last it lets go its hold with a violent 'click,' and the bubble of residual air and vapour reappears.

By this means Berthelot succeeded in stretching water by about $\frac{1}{120}$ of its whole volume, alcohol by about $\frac{1}{93}$, and ether by about $\frac{1}{59}$; and the author learns that Berthelot's experiments were repeated with even higher results by Mr. Creelman in Professor Tait's laboratory in Edinburgh.

Reasons were given for believing that the rupture is in no case due to the limit of the cohesion having been reached, but rather to the imperfect adhesion of the liquid to the walls of the vessel, owing to the presence of air, either in a film or in microscopic cavities. The effect of long boiling is to get rid of this adherent air, and the apparent increase in the cohesion is to be attributed rather to this cause than the liberation of air from solution.

The author then described the form of apparatus arrived at after many trials, by which the tension of the liquid and the extension produced by it could be simultaneously measured.

The tension was ascertained from the enlargement due to the pull of the liquid on the ellipsoidal bulb of a thermometer sealed into the containing vessel.

By means of this instrument (exhibited), for the construction of which the author had to thank his friend Mr. Charles F. Casella, he had already in a first trial succeeded in subjecting alcohol to a pull of fifteen atmospheres, or 228 lbs. to the square inch, with an extension that appeared to be about $\frac{1}{200}$ of the whole volume, or about three times what would have been expected had the coefficient of extensibility been the same as that of compressibility. This result, however, which depends on a single measure, when the apparatus, unfortunately, broke under the great strain upon it, requires further confirmation.

Measures of this kind afford an experimental determination of points in the unstable portion of the isothermal curve of a substance passing from liquid into vapour, which portion lies, as the author pointed out in a paper on 'The Surface Forces in Fluids,'¹ below the line of zero pressure, and not as indicated in Andrews' diagram, reproduced in Maxwell's 'Heat.'

The experimental proof that tensional stress within a mass of liquid is necessarily accompanied by a corresponding strain, is, in the author's opinion, an important point in the theory of surface tension, since it shows that the diminution of density or extension of the surface liquid, which can be shown to be a necessity of the equilibrium at the surface, is sufficient to account for the surface being a seat of energy. It becomes, in fact, unnecessary to ascribe to the energy any other form than that in which it exists in stretched matter.

5. *A new Sphere Planimeter.*² By Professor HELE SHAW, *M.Inst.C.E.*

The want has long been felt of some instrument for measuring areas which, while possessing the accuracy of the Amsler planimeter, would have the great advantage of giving a reading by means of a pointer moving over a dial face of such magnitude as to obviate the use of a vernier. The author, four years ago, brought forward a class of sphere integrator, under the name of sphere and roller mechanism, in which, by employing the rolling of two surfaces in contact with each other, instead of the combined slipping and rolling of the Amsler type of instrument, a satisfactory solution of the problem appeared to have been attained. Various forms of these integrators were thoroughly tested, but with unsatisfactory results, inasmuch as they always gave a slight error of variable amount, and it has since been found by means of specially designed experiments that the universally accepted principle of rolling contact relied upon in their design did not hold in practice under the particular conditions in which it was there applied. The sphere planimeter which was exhibited for the first time really belongs to the Amsler class of integrator, though resembling in external appearance the author's previous instrument above referred to, since one essential feature of it is a sphere.

* The instrument consists of a bent bar, one end of which forms the fixed centre, upon the surface containing the area to be measured. The other end is jointed to a frame which guides a sphere by means of four rollers, the centres of these rollers being carried upon small rigid brackets. The frame which supports the dial is continued by means of a bar, at the end of which is a pointer which is passed round the perimeter of the figure to be integrated. Upon the sphere rests a small measuring roller or integrating wheel, the axis of which carries the recording index and a pinion.

This pinion gears with a wheel ten times as large, working on the back of the dial, by means of which higher readings are recorded. Undue pressure between the measuring roller and the sphere is prevented by means of the roller which is attached to the bar.

The proof of the theory of the action of the instrument was then given, and the author concluded by pointing out that the action of the sphere is simply to transmit the motion of the roller, and therefore so long as no slipping takes place on the surface of the paper beneath the record is given with the same degree of accuracy

¹ *Phil. Mag.*

² Published in extenso, *Engineering*, Sept. 21.

as with the Amsler planimeter, but with the important advantage of a large dial reading, there being only the simple difference that the pointer must in the sphere planimeter be moved in the opposite direction round the perimeter of the figure to be measured.

One feature of interest in the instrument is the use of the four guiding rollers, which are in contact with the great circle of the sphere formed by the intersection of the horizontal plane through its centre, and thus allow the sphere to turn without resistance in any direction. To this end the rollers are carried in brackets, and do not exert any pressure upon the sphere, but just keep it in position in the frame. They are pivoted on very fine centres, and they are of steel with polished edges, so that even when the sphere is moving in a direction causing its axis of rotation to pass through one of these edges, the motion of the sphere is not appreciably retarded by frictional resistance. Hence the planimeter is found to be correct up to the limit of accuracy to which records can be read on the dial face.

6. *On Composition of Sensation and Notion of Space.*¹ By L. DE LA RIVE.

Notion of space is admitted to result from the association of our muscular activity with the perception of visual or tactile sensation. On the other hand, sensation of colour is a function of three variables, and muscular sensation is supposed to be also a function of three variables. Then the three dimensions of space are subjective.

A theoretical law of composition or synthesis of sensation is found to be the law of composition of forces. The principle applied to is—*consciousness of two simultaneous sensations is consciousness of the ratio of their intensities*, of which the well-known law of Fechner is a consequence. The differential equation of cosine is obtained by considering the variation of intensity, which, being eventually positive or negative, gives rise to a quadruple field of specific variation continuous with itself. The repetition numbered by 2^2 for the double synthesis is by 2^3 for the treble in the case of the eight solid right angles composing the whole ternary specific field, and would be 2^4 for a hypothetical quadruple synthesis.

The muscular sense is supposed to have its nervous organ composed of all the nervous fibres of an organ of mobility (the ocular globe, the arm) and the corresponding nervous centre. According to the law of composition, the exercise of muscular sense produces the notion of *subjective spherical space* thus defined; *the notion of the field of straight directions from a centre together with the notion of a length from the centre*. Hence the assertion that this notion is the muscular sense has in its favour: First, each sense gives us a peculiar notion; muscular sense is not apparent as others because the quality it teaches to endow the external world with is looked at as an absolute quality. Secondly, the fact of the blind possessing the notion of geometrical space with the same thoroughness as the seeing shows that the notion is neither visual nor tactile, but muscular.

Association of a permanent cause of external sensation, or entity, with the species in the ternary subjective field which, when acting, leaves undisturbed the external perception is the localisation of the cause. Hence the formation of *monocular space*. Any muscular sensation of the ocular globe is a rotation round an axis, and the rotation round the direction of the luminous ray leaves undisturbed the direct vision. A retinian angular field is produced by a similar process.

A process of formation of *tactile space* is analysed in the case of a schematical arm, with the humerus acting in the same manner as the ocular globe, and the elbow giving by the variable angle of its articulation a variable radius to the spherical surface described by the hand. The passage from a tactile point to another with a minimum of sensation is given by a constant species in the ternary field. Hence the geometrical definition of the straight line. Definition of parallels is given by assimilating any tactile point to the centre. The hypothesis of subjectivity of geometrical space may perhaps call the attention.

4. *Modern Views about Hurricanes, as compared with the Older Theories.*
By Hon. RALPH ABERCROMBY, F.R.Met.Soc.

The old conception of a hurricane was that of a circular-shaped eddy, round which the wind blew in circles; the whole system was not supposed to be connected with any surrounding trade-wind or monsoon, and the idea that a hurricane changes its shape, as well as its depth and intensity during its progress, was never thought of.

Modern research shows that a hurricane is really an oval eddy, and that the vortex, or centre of the wind rotation, is not in the geometrical centre of the oval, but usually nearer one edge or other of the depression. The former is a very simple, the latter a very difficult conception; nevertheless, such are the facts, as the author has proved by an examination of hurricanes on 60 different days.

The wind blows as a spiral of variable incurvature round the vortex, not round the centre of the oval. The general sense of the rotation is counter-clockwise in the Northern, clockwise in the Southern Hemisphere; but the amount of incurvature varies in different parts of the oval for a number of reasons. As a rule, in all hurricanes, the incurvature is less in front than in rear of the vortex.

A hurricane is also always changing its shape, so that the oval lies sometimes in one way, and sometimes quite in a different direction; while sometimes the vortex is displaced towards one side of the oval one day and towards quite another side on the next.

The path of the hurricane is not in a regular line, for the vortex sways about, and sometimes even describes a loop.

For all these reasons, no rule is possible for determining absolutely the bearing of the vortex by observations on board a single ship; whereas it used to be stated positively that facing the wind the vortex bore 8 points—at right angles—to the right in the Northern, and to the left in the Southern Hemisphere.

We can only say now that, when fairly within the storm-field and facing the wind, the vortex will be to the right and a little to the rear; that is, from 8 to 12 points to the right of the wind in the Northern Hemisphere; and to the left and a little to the rear; that is, from 8 to 12 points to the left of the wind in the Southern Hemisphere. If the wind blew exactly in a circle round a circular hurricane the vortex would always bear 8 points to the right or left according to the Hemisphere, and the rule to take 8 to 12 points is simply allowing for the effects of variable incurvature.

The above rule does very well for a first approximation to the bearing of the vortex, but greater precision can be attained in certain circumstances. If the condition indicate that a ship is nearly in front of the vortex, the bearing of the vortex will probably not be much more than 8 points to the right or left, according to the Hemisphere, because, as before mentioned, the incurvature is very small in

front of a hurricane. Great care must be taken not to apply this rule to an increasing trade with a falling barometer, as will be explained hereafter.

In the rear of a hurricane, on the contrary, the vortex may bear 12 or even more points to the right or left of the wind, because the wind is very much incurved in that part of a hurricane. A ship should therefore always then lie-to till the barometer begins to rise and the weather to improve, otherwise she will probably run right into the vortex. She might easily scud 10 knots, while the hurricane might not be advancing more than 5 miles an hour, so that it is very easy to catch up the vortex. The discovery of this great incurvature is one of the most important modern developments of the subject.

It used to be thought that if the wind increased in force, without changing in direction, with a falling barometer, a ship must necessarily be in the line of progression of the vortex, and that she should run at once. This was owing to the idea that a hurricane was an isolated disturbance.

Now we know that if it is only the usual trade-wind which increases without changing in direction, and with a falling barometer, a ship should lie-to till the mercury has fallen at least 6-10ths of an inch before she runs as a last resource. Modern research has proved that a hurricane is usually imbedded in some prevailing trade or monsoon, and that there is therefore a belt of intensified trade-wind outside the true storm-field. This belt is always on the side of the hurricane furthest from the equator. A ship in this belt experiences an increasing trade without change of direction, and with a falling barometer, though she may be far away from the line of progression of the vortex. She would equally experience an increasing and unchanging wind with a falling barometer, if she were in the line of progression; but as there is no means of knowing whether she is in the line of progression, or only in the belt of intensified trade, the empirical rule says: 'Lie-to till the mercury has fallen 6-10ths of an inch before beginning to run.'

The old rules for finding which semicircle of a hurricane a ship may be in, and the old rules for heaving-to in either Hemisphere, are all proved to be both true and valuable by modern research. These rules remain as follows: Facing the wind in both Hemispheres, if the wind changes by the right, the ship is in the right-hand semicircle, and she should heave-to on the starboard tack. If the wind changes by the left, she is in the left semicircle, and should heave-to on the port tack. If circumstances compel her to run, she should keep the wind well on the starboard quarter in the North Hemisphere, and well on the port quarter in the South Hemisphere.

It is much to be regretted that the examination papers of the Board of Trade for master and mates are painfully behind the modern standards of knowledge, and that in these matters the Germans and other nations are now ahead of England. The whole knowledge which is required in our merchant service is contained in six questions, and a candidate is expected to say that the centre bears 8 points, or perhaps a little more, from the direction of the wind, while no notice is taken either of the small incurvature in front or of the great incurvature in rear, or of the belt of intensified trade, where the usual indications of being exactly in front of the vortex fail.

No one should blame the master of a ship for not following the established rules without the closest investigation, for, as Piddington says, 'absolute rules are all nonsense,' and much depends on the capabilities of a ship, and on the ever-varying conditions of a heavy cross sea.

6. *On the Temperature of some Scottish Rivers.*

By HUGH ROBERT MILL, D.Sc., F.R.S.E.

Observations were carried on in a number of rivers in different parts of Scotland, with the result that from January to July 1888 the variations of temperature were practically identical; all the curves showing a series of well-marked maxima and minima exactly coincident in date and approximately equal in amplitude, although the actual temperature varied for each stream. The maxima appear to characterise periods of high air-temperature and slight rainfall over Scotland generally, the minima periods of low air-temperature and considerable precipitation. The temperature of the water in the Aray, the one stream of the west coast examined, was always lower than that of the air; but over the east coast rivers the air-temperature was more extreme, and frequently fell below that of the water.

7. *On the recent Magnetic Survey of Japan.*

By Professor CARGILL G. KNOTT, D.Sc., F.R.S.E.

This survey was carried out during the summer months of 1887, the expenses of the expedition being wholly borne by the Imperial University.

The object was to obtain, within as short a time as possible, a general survey of the whole of Japan. The work was accomplished by two parties, known as the Northern and Southern Parties. The Northern party was under my own charge, and its route may be roughly described as a cycle of that part of Japan which lies to the east and north of a line drawn from Fujiyama north-west to the peninsula of Noto. Mr. Tanakadate took charge of the Southern party, whose stations all lay to the west of the line just described. The Northern party took observations at four stations in the Island of Ezo, and the Southern party made a trip to Korea and obtained a series of valuable measurements in the neighbourhood of Pusan.

The Northern party were equipped with a complete set of instruments of the usual Kew pattern—the dip circle used being one which was kindly loaned by the Kew Committee of the Royal Society. The chronometer was checked daily by sextant observations. The Southern party used Mr. Tanakadate's own form of electro-magnetic declinometer (described 'Proc. R. S. E.' 1884-6), which was also fitted up for the measurement of the horizontal force by the ordinary method of sines. The theodolite, whose base was an essential part of Mr. Tanakadate's declinometer, served in its usual form for taking the transits and altitudes necessary for rating the chronometer and finding the true meridian.

Generally speaking, the magnetic features of Japan present great irregularities, a fact which the highly volcanic condition of the country would lead us to expect. The south-western portion of the main island, with the adjacent islands fringing the Inland Sea, presents fairly uniform magnetic features. The regions where the greatest disturbances exist are (1) the great central mountain region to the north and north-west of Fujiyama, and (2) the region included between the 38th and 40th parallels of latitude.

The general characteristics of the iso-magnetic lines corresponding to the observations made are as follows:—The lines of equal dip, of equal horizontal force, and of equal total force are approximately straight, while the lines of equal declination are distinctly parabolic or hyperbolic, approximating very closely to the general form of the main island. Out of the eighty-one stations at which complete observations were carried out, a selection of fifty was made; and the values of the magnetic elements at these selected stations were combined by the method of least squares according to the usual mode. Linear expressions in latitude and longitude were assumed for the dip, horizontal force, and total force; and, for the particular case of the declination, a term was added in the square of the longitude. The latitude and longitude co-ordinates were referred to the mean station (36° 30' N. lat.; 137° 9' E. long.).

The mean formulæ so obtained are as follows:— ϕ and λ being the latitude and

longitude co-ordinates, referred to the mean station, and measured in minutes of arc; and θ , H , F , δ being respectively the dip, the horizontal force, the total force, and the declination.

$$\begin{aligned}\theta &= 50^{\circ} 28' \cdot 6 + (1 \cdot 141 \phi - \cdot 1556 \lambda)' \\ H &= \cdot 29482 - \cdot 0000617 \phi - \cdot 0000117 \lambda \\ F &= \cdot 46407 + 000094 \phi - \cdot 000045 \lambda \\ \delta &= 4^{\circ} 53' \cdot 3 + (\cdot 241 \phi - \cdot 109 \lambda - \cdot 000231 \lambda^2)'\end{aligned}$$

The horizontal and total forces are measured in C.G.S. electro-magnetic units, and the declination is west.

From these expressions we may find the quantities u and r for the mean station:— u being the angle between a given iso magnetic line drawn eastward, and the longitude line drawn northward, and r being the rate of change of the given element per kilometre of distance measured in a direction perpendicular to the iso-magnetic line. The values of u and r for the several quantities are given in the subjoined table, together with the value of the element at the mean station:—

	Mean Value	u	r
Dip	$50^{\circ} 28' \cdot 6$	$80^{\circ} 23' \cdot 6$	$0' \cdot 626$
Horizontal force	$\cdot 29484$	$103^{\circ} 14' \cdot 9$	$\cdot 000034$
Total force	$\cdot 46407$	$59^{\circ} 16' \cdot 5$	$\cdot 000059$
Declination	$4^{\circ} 53' \cdot 3$	$29^{\circ} 19' \cdot 6$	$0' \cdot 149$

Regarding the secular changes in the elements very little can be definitely said. If we admit the accuracy of Ino's observation of eighty years ago, that the needle pointed true geographical north at that time, then the mean secular change during these eighty years will be about $3' \cdot 7$ per annum. Gauss's numbers give $1^{\circ} 46' \text{ W.}$ as the value of the declination at the mean station of the present survey. Taking fifty years as the interval between Gauss's epoch and now, we get again about $3' \cdot 7$ as the mean annual rate of change of the declination in Japan. Recent observations, however, do not bear out this conclusion. Thus, if we compare (as far as comparison is possible) the observations made in the summer of 1887 with those made during the autumn and winter months of 1882 and 1883 by Messrs. Sekino and Kodari at their numerous but not very well distributed stations, we find no evidence of any well-marked secular change of the declination during the interval in question. There are indications, however, of changes in the other elements, namely, an average decrease of $2'$ per annum in the dip, an increase of nearly $0 \cdot 1$ per cent. in the horizontal force, and a decrease of fully $0 \cdot 1$ per cent. in the total force.

The full details of the survey are given in the second volume of the 'Journal of the College of Science, Imperial University, Japan.'

8. *On Reading Electrically Meteorological Instruments distant from the Observer.*¹ By J. JOLY, M.A., B.E.

An instrument placed in a distant observatory may on this system be controlled by three wires communicating with the home station. The principle on which a reading is obtained is, briefly, as follows. The instrument is in circuit with a rheotome at the home station. One contact on the rheotome corresponds to a movement over a definite distance of a travelling limb on the distant instrument, the limb being actuated by an electro-magnet. In the case of the barometer or thermometer, for example, the travelling limb carries a metallic pin through a definite distance at each make, starting from a known zero position, till finally the pin makes contact with the mercury in the instrument, when a needle in the home station is deflected. The position or level of the mercury is thus easily computed from the reading of the rheotome or number of interruptions effected. The

¹ *Proc. Royal Dublin Society*, vol. iv. new series, p. 158.

mechanism to be attached to each instrument is very simple. A thermometer fitted with it gives satisfactory results.

An arrangement whereby an indefinite number of instruments may be controlled by one light cable of three wires is proposed. It has not, however, been practically tested.

9. *On the Mechanical Conditions of a Swarm of Meteorites, and on Theories of Cosmogony.* By Professor G. H. DARWIN, F.R.S.

10. *On some accurate Charts of Kew Corrections for Mercury Thermometers.* By W. N. SHAW, M.A.

An English thermometer (Hicks, No. 79915) graduated in the stem to $0^{\circ}2$ C. was compared at Kew in the ordinary way in December 1880 to $0^{\circ}1$ C. at each fifth degree between 0° and 35° . In January 1882, through the kindness of Mr. G. M. Whipple, Superintendent of the Kew Observatory, it was compared at each degree and the readings were estimated to the hundredth of a degree. A similar comparison was carried out in the same way in April 1888. The errors from true (Kew standard) temperature are plotted and the points joined to facilitate interpolation. For the two sets of more accurate comparisons the curves are smoothed within the limits of possible errors of observation. These two curves are drawn on the same sheet with the plotting of the original comparison and the juxtaposition makes it easy to compare the curves. During the interval from January 1882 to April 1888 the zero had risen $0^{\circ}1$ C., and, on the usual assumption, the two corresponding curves should run parallel to each other at a distance representing that difference of temperature. The general similarity of the two curves is very fairly exhibited in the diagram, and affords evidence of accuracy and trustworthiness of the comparisons upon which Mr. Whipple and his staff are to be congratulated. A slight divergence from parallelism is, however, clear, as the curves get gradually wider apart as the temperature rises, the difference at 30° being $0^{\circ}17$ C., whereas at 2° it is $0^{\circ}1$ C. The original rougher comparison epitomises the more accurate ones in a very striking manner.

Similar results follow from charts for two other English thermometers by Hicks and for two German thermometers by Geissler. But the divergence from parallelism is not shown in the charts of two thermometers by Negretti, nor of two by Casella, the curves in these four cases running very nearly parallel, although there were changes of zero of $0^{\circ}35$ F. and $0^{\circ}2$ F. respectively. In the case of the German thermometers there was no appreciable change of zero in the interval. It would appear that the divergence from parallelism is due to the nature of the glass employed in the construction of the instruments.

11. *On an Apparatus for determining Temperature by the Variation of Electrical Resistance.* By W. N. SHAW, M.A.

This apparatus is designed to measure to a high degree of accuracy the mean temperature of a large burette in a water-bath. A Wheatstone quadrilateral is formed by joining the ends of a platinum wire about 30 inches long (resistance about 11 ohms) to those of a platinum-silver wire BCDA. The platinum wire is bare and the alloy is silk covered, $\cdot007$ inch in diameter; its resistance is 13.5 ohms per metre. At A, C and B, D respectively battery and galvanometer wires are soldered; the lengths of the wires are so arranged that for some temperature near 15° C. there is a perfect balance indicated in the bridge. The wires are laid in parallel lengths and disposed upon a strip of pure india-rubber, about three-quarters of an inch wide, in the manner indicated in the figure. The india-rubber is painted with a solution of india-rubber in benzene and a second strip, similarly painted, is laid down upon it and the wires are thus completely enclosed; the strip contains 18 inches at each end beyond the junctions of leading wires, so that

the whole length of strip is about $5\frac{1}{2}$ feet, and from the two ends the galvanometer and battery leads respectively project.

A very flexible quadrilateral is thus obtained in the form of a ribbon, which can be wrapped round any apparatus whose temperature is required.

Since the two wires, which together form the quadrilateral, have different temperature coefficients, there is no balance except for one particular temperature; but the balance can be restored by shunting either the wire AB or the arm BC by connecting a resistance-box in a suitable manner with the projecting leads. The resistance of the shunt required to produce a balance can be employed to indicate the temperature when the instrument has once been graduated. The graduation of the apparatus exhibited was made for the author at the Cavendish Laboratory

by Mr. J. W. Capstick, demonstrator at University College, Dundee. The ribbon was wound round a metal cylinder, and the whole immersed in ice or water, and a number of readings of the shunt taken at different temperatures between 0° and 28° C. The conductivity of the shunt at different temperatures is very nearly represented by a straight line cutting the zero line at the neutral point 15.16° C. The maximum divergence from the straight line corresponds to the temperature difference of a fifth of a degree between 0° and 15.16° and to about a tenth of a degree between 15.16° and 28° . In the graduation the temperatures are referred to the Kew standard by means of mercury thermometers previously compared at Kew. The temperature can be read with a suitable galvanometer to about the 500th of a degree.

12. *Fourth Report of the Committee on Standards of Light.*

See Reports, p. 29.

TUESDAY, SEPTEMBER 11.

The following Papers and Report were read:—

1. *Joint Discussion with Section G on Lightning-conductors.*

The PRESIDENT called upon Mr. W. H. Preece, F.R.S., and Professor Oliver J. Lodge, F.R.S., to open a joint discussion with Section G on Lightning-conductors.

Mr. PREECE said it was a most remarkable thing that if they wanted to know much about atmospheric electricity and its effects they had to go back to the works of Benjamin Franklin 140 years ago. Scarcely anything had been done in this direction since then. Up to the year 1881 there was not even a code of rules extant in this United Kingdom to guide people in protecting their buildings from the destructive effects of atmospheric electricity. It was proposed in 1878 to establish a conference of various societies to discuss the effects of atmospheric electricity and to form a code of rules for the erection of lightning-conductors.

At the York meeting of the Association in 1881 a report was adopted; it was then published, and was one of the most admirable works that had ever been collated on atmospheric electricity and its effects.

Now that report was divided into three parts. In the first part was discussed the purpose which a lightning-conductor was intended to serve. In the second part there was a statement of those features in the construction and erection of the lightning-conductors respecting which there had been, or was, a difference of opinion, and the final decision of the Conference thereupon. In the third part

there was drawn up a code of rules for the guidance of those who erected these conductors. He might say that that report itself was most decisive and it was most important. He could not help reading out to them, because it would form the basis of a good deal that would be said that day, how they defined a lightning-conductor:—‘A lightning-conductor fulfils two functions. It facilitates the discharge of the electricity to the earth, so as to carry it off harmlessly, and it tends to prevent disruptive discharge by silently neutralising the conditions which determine such discharges in the neighbourhood of the conductor. To effect the first object a lightning-conductor should offer a line of discharge more nearly perfect and more accessible than any other offered by the materials or contents of the edifice we wish to protect. To effect the second object the conductor should be surmounted by a point or points; fine points and flames have the property of slowly and silently dissipating the electrical charges; they in fact act as safety-valves. If all those conditions be fulfilled, if the points be high enough to be the most salient features of the building, no matter from what direction the storm-cloud may come, be of ample dimensions and in thoroughly perfect electrical connection with the earth, the edifice with all that it contains will be safe, and the conductor might even be surrounded by gunpowder in the heaviest storm without risk of danger. All accidents may be said to be due to a neglect of these simple elementary principles. The most frequent sources of failure are conductors deficient either in number, height, or conductivity, bad points or bad earth connections.’ The paragraph ended with this most decisive and clear assertion, an assertion that he was there to defend, and that was that there was ‘no authentic case on record where a properly constructed conductor failed to do its duty.’

Now here they had defined the functions of a conductor, and lest it should be thought that they neglected the teachings of modern theorists he thought it was only right to point out that they asserted in the Report of the Lightning-rod Conference, ‘We will assume the conductivity of equal lengths and weights of iron in the case of steady currents of electricity’; and further on they asserted ‘that the suddenness of lightning discharge modifies the conductivity.’ Now that report, he might say, was signed by Professor Grylls Adams, Professor Ayrton, Latimer Clark, E. E. Dymond, Carey Forster, D. E. Hughes, Peter Lewis, W. H. Preece, G. J. Symons and John Wychgrove. He had a great deal of experience in the performance of lightning-protectors. He personally had under his supervision at that present moment 500,000 lightning-conductors, and fixed throughout the offices of this country they had their apparatus protected by about 30,000 or 40,000 lightning-protectors. Professor Oliver Lodge was selected to deliver lectures at the Society of Arts. If all the vaticinations of Oliver Lodge were true, the work of this Committee and the work of the last 140 years would be useless; no lightning-protector could possibly protect and no discharge could possibly be led to earth.

Now those were strong assertions. He thought that Professor Oliver Lodge had in his papers before the Society of Arts, and in his paper published in the ‘Phil. Mag.’ committed certain fallacies that it was now his (Mr. Preece’s) duty to bring before them. Now in the first place Professor Lodge assured them that a lightning-rod formed a part of a flash. Well it did not. Nobody had ever seen, to his knowledge, a flash of lightning strike a conductor. The function of a lightning-conductor was to prevent the possibility of its being struck by a flash, and if it were struck by an infinitesimal part of a flash, then he said that lightning-protector was not a lightning-protector; it had some defect in its construction that had to be remedied. But suppose it did. Then the lightning-protector would form but a very small portion indeed of the path of the lightning discharge from the cloud to the earth. A great deal depended upon the height of the thunder clouds. They saw in text-books ridiculous assertions about the length of lightning flashes. Well, now, who could measure the length of a lightning flash? There had been several extremely accurate measurements of the height of thunder clouds. In South Africa Dr. Mann measured, and his measurements made the height 650 feet. But the most accurate measurements had been made by M. Lacoïn, a Frenchman in charge of the Ottoman telegraphs in Constantinople, and there he made the height of a cloud, therefore the length of a flash, about 325 feet. Well, they had those two measurements,

accurate measurements, he believed; and during the past summer, amongst the mountains of North Wales, he saw several thunder clouds, and those thunder clouds seemed at a height of about 500 feet, and he felt almost certain that the length of our flashes of lightning did not average more than 500 feet. In consequence of the researches of Sir William Thomson and also the measurements made by Dr. Warren De La Rue and Hugo Müller the striking distance across the layer of air for steady currents in one direction was pretty well known. It was something like 30,000 volts per centimetre. Now if a flash of lightning were 500 feet long and it varied directly as the striking distance, then Oliver Lodge's measurements given in his papers would be fairly accurate. But there was every reason to believe that the striking distance did not vary directly as the distance, especially for alternate currents that were modifying their conceptions in every direction of the action of electricity. There was a Mr. Acheson in America who had been making some very careful observations on the striking distance across air when currents were produced by transformers; and there he made out that the striking distance varied not directly as the electromotive force, but as the cube of the electromotive force. If that be so then it would follow that the electromotive force forcing a current of electricity through the air and producing a flash was very much less than they hitherto had considered it. And again a flash of lightning always went along a path that had been prepared for it. All photographs, as they would see presently, gave indications that wherever lightning flowed there some preparation had been made for its approach.

Next there was an assumption which he considered a fallacy, and that was that a flash of lightning was instantaneous. Now they all knew experiments that were made to show revolving wheels; the spokes of the revolving wheel suddenly appeared before them whenever a spark passed, and they most of them believed that a flash of lightning was really instantaneous. There was no proof of its instantaneity. What they knew was that the flash was merely a flash of light that indicated the path. How long that flash lasted they could not tell. But there were dark and invisible flashes, if they might so call them. There were dark and invisible charges of electricity, and there were cases on record where people had been struck and killed underneath trees where no light of any kind whatever had been seen. But he argued on the non-instantaneity of lightning flashes from their effects on telegraph wires. Now of course we had spread all over this country an enormous network of telegraph wires. Whenever a lightning flash took place anywhere some wire was sure to be affected somewhere, and wherever lightning took place it might not hit the wire. It sometimes did. Whether it did or whether it did not, it did not apparently make very much difference in the effects observed. But there they always got currents of sensible duration. For instance, on board ships, ships had often been struck, especially when their lightning-protectors were a little defective, and there invariably it had been observed—or rather he should not say invariably, but frequently it had been observed—that compasses were turned about, and they went playing about wherever the ship passed through an electric storm. Now it was quite impossible that the compass of a ship which had a very slow rate of vibration could be deflected or turned round unless there was a considerable duration in the flash. However that was a point on which the photographs taken gave a considerable amount of information, and during the discussion he hoped that Mr. Abercromby would give them a sight of some of those beautiful photographs that he had collected.

Now he went to perhaps the hardest nut of all in the questions before them to discuss—one that he approached with a certain amount of diffidence because it was supported by very high authorities, and that was the assertion that a flash of lightning was oscillatory in its character; that was, that it did not flow straight from the cloud to the earth and disperse; that it went slashing backwards and forwards, somebody said a million times in a second; but he was not going to discuss that—at any rate that that flash went flying backwards and forwards with considerable frequency. Now he might say at once that that assertion of the oscillatory character of a lightning flash was based more on mathematical reasoning than it was on absolute observation. Well, he was not going to say much on the

mathematical part of the question, first, because he did not think it would interest them, and secondly because he did not think he was quite equal to it himself.

He thought that this theory, beautiful as it was, of the oscillatory character of a lightning flash must be received with great caution. Now there were several facts against the theory. There is no doubt whatever that electro-magnets are powerfully excited for a sensible duration by lightning flashes. They knew that needles were magnetised and demagnetised; they knew that electrolysis could be produced by lightning flashes. He had pointed out to them that the mariner's compass was caused to fly about. Sounds were produced. He had stood in the telegraph office and he had heard distinctly letters of the alphabet signalled by a flash of lightning.

Three oscillations were required to make the letter 'R.' He had heard the letter 'C' which involved four currents. There was a case on record in the A B C instrument of Wheatstone of the letter 'G' having been made. Now the letter 'G' required eight alternations to be made in order to be recorded. And there were other effects. Hence he said that those durable effects on telegraphs were contrary to the oscillatory theory of the flash, unless the frequency of those oscillations were very small indeed; and he said that there were very great doubts as to whether it was true for lightning flashes. It might be true for condensers; it might be true for Leyden jars; but they were not dealing with Leyden jars; they were dealing with flashes of lightning, which if they were analogous to anything in a Leyden jar they were analogous to the bursting of the dielectric, and not to the external discharge where oscillations might occur. Of course they had in a Leyden jar the dielectric, with its charges of positive and negative electricity on each side of it in a considerable state of mechanical stress; and when that stress was suddenly removed, as it was by a spark, then it was not difficult to conceive that there might be mechanical oscillations in the dielectric; but he could not conceive that those took place in a flash of lightning which burst through a mere layer of air. Speaking once more upon oscillations he must mention to them that they had evidence, distinct evidence, of slow oscillations in a flash of lightning; and he thought the photographs would also give them some evidence of that. But Professor Elihu Thomson, in America, a very remarkable observer and one of the ablest men on the other side of the Atlantic, had recently, during a thunderstorm, by wagging his head about or wagging his glass about, seen six distinct flashes pass exactly over the same path. They had other evidence in favour of slow oscillations, but at present they had no evidence whatever of those rapid oscillations, and if they did not exist then the whole of Professor Oliver Lodge's ingenious theory fell to the ground.

On this point he could not help reading just one little quotation from Faraday's researches, who showed how when a spark flew across an air-space the whole of the electricity disappeared. He said: 'The ultimate effect is exactly as if the metallic wire had been put into the place of the discharging particles, and it does not seem impossible that the principles and action in both cases may hereafter prove to be the same.' He thought that that statement of Faraday had a most important bearing on the theory of electricity.

He would deal with another and extremely important point that Oliver Lodge had raised, and one of immense value. Mr. Lodge had given some very beautiful experiments indeed to prove his case. He took two Leyden jars and they were charged with a Holtz machine.

Now there were many objections to this self-induction theory. There was no doubt whatever that Professor Lodge, in this inquiry, had started an entirely new and fresh hare, which they, as electricians, were bound to hunt up, and follow, and kill. He felt satisfied that Professor Lodge was on the brink of some discovery in connection with static electricity. He did not think his explanations were right. He did not believe in the influence that he assumed of self-induction.

As a fact 'self-induction' is used in innumerable senses and in different ways. Professor Lodge himself, with all his care, could not avoid speaking of this self-induction in various ways.

Now, as he had said, Professor Lodge had made a discovery—he (Mr. Preece)

did not know what it was, but in being possessed of this mania he might call it self-induction—he had had self-induction before his eyes and seen nothing else, and consequently had not studied Professor Poynting's paper to the advantage that one would expect. If he had studied Professor Poynting's paper (who shows that energy passed through the dielectric and not through the conductor) he might have applied that principle to his experiments and proved with equal satisfaction to himself that the peculiar effects that he produced were due to something or other in the dielectric. But he was not sure that he would not find on further inquiry into the matter that there was something between the dielectric and the conductor. They knew that a conductor in contact with a dielectric in contact with air was subject to an electromotive force. They knew when a row of people, for instance, were collected together and a spark was passed through them those who suffered were the two end ones. There were several instances on record where horses had been ranged in a row, and the two extreme horses had been killed and the intermediate ones not touched. That showed that there must be some effect between the surface of the terminals and the air, of which at present they were ignorant. He thought that that was a point that deserved experiments. Wires could be obtained coated with various dielectrics. He could supply Professor Lodge, if that gentleman would continue his experiments, with any quantity of wire covered with gutta-percha, with paraffin, or with any other compound that was in the market. Then, again, there was nothing analogous to the transformation of energy in those experiments of Professor Lodge. Let his explanation be absolutely true; let there be self-induction in those alternative currents—he could not conceive from analogy of any single effect of self-induction that would cause the electromotive force between those two balls to increase from 100,000 to 140,000 volts. They had to account for a great increase of electromotive force. Professor Lodge indicated in his paper at Section A on Friday that a spark of one inch at a distance of three yards increased to (he thought) fourteen inches. There they had an increase of electromotive force that would be something like an increase from 100,000 volts to 1,000,000 volts, and they could not account for that by any known phenomenon connected with self-induction.

Well, those points, he thought, rather tended to shake one's confidence in the oscillatory character of lightning, and in the influence of self-induction in determining the efficacy of lightning-protectors.

The next fallacy of Professor Lodge that he wished to touch was one where he asserted that a lightning-protector protected no area whatever. If a lightning-protector raised above that building did not protect an area around and about that building, what earthly use was there in a lightning-protector? Well, they knew from evidence in the Report of the Lightning-rod Conference that areas were protected, and he had in a paper in the 'Philosophical Magazine' worked that out in a way that he thought could scarcely be controverted. Again Professor Lodge asserted that extended points were needless. Well, their Report on the Conference said that extended points were necessary. Of course those two opinions were diametrically opposed to each other. The Conference placed their stand upon the experience of the past, and Professor Lodge placed his stand upon his mathematical assumptions.

Next as to iron. Professor Lodge advocated iron now; so did he. But he found on November 3, 1887, in 'Nature'—only last November—Professor Lodge says: 'A lightning-conductor should not be a round rod, but a flat strip, or a strand of wires with the strands as well separated as convenient, and though I have not mentioned the special effect of iron I may as well say here that iron is about 90,000 times worse than copper.'

He had said something about mathematical developments, and he thought that one of the serious errors committed by those who relied on mathematical developments was that of hasty generalisation.

He had always held the belief that they would sooner or later trace an electric current to be a mere vibration, a mere oscillation of the molecules that composed the mass of their conductors. He carried out in Dr. Warren De La Rue's laboratory a series of the most brilliant experiments with his great battery deflagrating

pieces of wire, and those pieces of wire were laid flat between white paper, and the result of the deflagration showed upon that white paper. There they had a distinct indication of waves—that the passage of the current through the conductor burst in the form of waves. Professor Hughes, one of their best experimenters, one of the most marvellous men with his fingers, had been working steadily together with himself. The notion that they had gone upon was that in order to account for heat, in order to account for light, in order to account for electricity, and in order to account for the difficult *cruz* of the whole question of the duality of electricity, they would have to prove that the result of the motion in an electric current was spiral, that it was of the character of a right- and left-handed screw. So that when they had it going in one direction there was positive electricity, and when it was going in the other direction there was negative electricity. He threw that out as a suggestion which deserved to be worked out.

He said, in conclusion, that he had done all that he possibly could to prove that the position taken up by the Lightning-rod Conference was the true one. He had shown Professor Lodge's conclusions to be in some respects fallacious. No doubt Professor Lodge would say that they were not. He (Mr. Preece) felt satisfied of this, that whether the result of the discussion were to establish the truth of the position taken up by the Lightning-rod Conference, or whether Oliver Lodge were right, at any rate the discussion would have had this advantage, that it would bring to their minds what they were all anxious to see—the true theory of electricity.

Professor OLIVER LODGE said he must in the first place confess that he had nothing whatever like the experience of Mr. Preece to base his statements upon. There was not at present even a lightning-conductor to the college in Liverpool with which he happened to be associated. He had asked them to put one, but lightning-conductors at present seemed to be so expensive that the answer he generally got was that it is cheaper to insure.

It was perfectly true that if his views were correct very few buildings are effectively and thoroughly protected at the present time; but then, also, if they were correct, lightning-conductors would in the future be bought for, he was going to say, as many shillings as they are now bought for pounds; but, at any rate, they will become much cheaper; and that of itself would be no slight advantage if, of course, they are equally effective.

Mr. Preece began by saying that there is no authentic case on record of a properly constructed conductor failing to do its duty. He had read carefully that report of the Lightning-rod Conference to which Mr. Preece drew attention, and there he found a large number of entire failures. There was one very noteworthy one which was often quoted—a brass rod, an inch thick, on a steeple in Italy, which was smashed all to pieces and the spire destroyed, the flash being seen, he believed, by a number of people. There is a heap of other cases. In his lectures this spring he quoted, as the best protected building in the world, the Hôtel de Ville at Brussels, on which M. Melsens had spent so much time and trouble. It was elaborately protected; it was protected by innumerable conductors with admirable earths made in a variety of ways, bristling with points all over the top—everything being carried out in the most approved style, regardless of expense. But in the month of June that building was struck, and it was set on fire. The fire was put out. He was sorry he did not know more particulars. The particulars had not been published, but he thought they ought to be published, because that was a building the protection of which had had books written about it. M. Melsens himself wrote a book about it. It should be very instructive to find out, when a thoroughly protected building was struck, how and why it was done, and what damage was done, and all about it. But he did not think, although he spoke from a limited experience, apart from reading, that it could be said that existing conductors never fail.

Then Mr. Preece had a hit at him where he admitted he had the advantage. Mr. Preece quoted an entirely erroneous statement which he made. But he (the speaker) had not introduced that as a statement of a mathematical calculation or anything; it was the merest parenthesis thrown in, and it was very hastily done. Of course

one ought not to do those things, but still if one wrote much one was very apt at some time or other to make very hasty statements. When the Society of Arts asked him to give a lecture on lightning-conductors he thought to himself, 'Yes, I will tell them about induction,' because he knew that the Lightning-rod Conference had not called attention to that nor yet to magnetic inertia or whatever they called it. He had happened to write a paper which appeared, he thought, in 'Nature'—he did not know where the quotation made by Mr. Preece came in—and in that paper having referred to the magnetic permeability of the two metals, copper and iron, he had stated that iron was 90,000 times worse than copper. He went on to say, therefore, that although iron was cheaper it was more difficult to melt, had a higher specific heat, and in a variety of ways was better than copper, yet in regard to this electro-magnetic inertia it was enormously worse. But before actually giving those lectures, on again making a few experiments, to his surprise, he found that, so far from being worse, it was often rather better—that iron, even a thin wire of iron, carried off the discharge better than a thick wire of copper. He did not press the point that iron is better than copper, and he had never said that copper has more self-induction than iron—that would be a mad thing to say. It might happen for some reason or other that the copper obstructed the current more than the iron, but he preferred to say that they are just equal.

Now Mr. Preece said that the function of a lightning-conductor is to prevent a flash from striking the conductor; that is to say, that a lightning-conductor never ought to be struck or it fails. But they are struck because they get melted. Yet at the beginning sentence Mr. Preece said that they never failed. He did not know which of these statements was to be taken as correct. If a lightning-conductor can prevent a flash from occurring by its repellent action well and good, but he had shown in those lectures that there are cases where a point has no protective action whatever, when a point could be struck by a thick and heavy flash. There were other cases where the point acts with a brush or fizz and neutralises the electric charge without a flash. They could not always do it. And so the lightning-rod has two functions, one is to be repellent if it can and the other is to carry off a flash when it cannot help receiving it. But they must remember that a flash, at least that the electric charge, has a certain amount of energy, and that has to be dissipated somehow. It was not a question of a certain quantity of electricity to be conducted to earth and then there was an end of it. There must be a certain amount of energy, they must dissipate it somehow, and they could not expect to *hocus-pocus* it out of existence by saying they could conduct it down to the earth. The quicker they tried to conduct it down to the earth the more searching and ramifying disturbances they were likely to get. It might be better to let it trickle down slowly by using a moderately bad conductor than to rush it with extreme vehemence down a good conductor; just as it would be safer to let a heavy weight suspended in a dangerous position down slowly rather than let it drop as quickly as possible.

Concerning the length of flashes he wished he had any information, but he had none; it was one of those things which their friends, the meteorologists, must determine for them. It was very important to know the length of a flash. He had found it stated in books that flashes were a mile long and perhaps more. Mr. Preece thought they were only 500 feet long. That was a matter of fact which could be investigated, but of which he had no direct first-hand information. Whether the spark-length is proportional to distance or not he would say that the experiments with oscillating currents to which Mr. Preece referred were conducted with alternating dynamos between points. Now the area of cloud and the area of earth below it are not points, they are flat.

There the law did not seem to hold, but then it ought not to hold, so that would be all right. But between flat surfaces it ought. The spark-length ought to increase with a difference of potential between the two flat surfaces. At the same time if there were points on the earth's surface big enough and which in any fashion could act as points, then of course it would not hold. But the oscillating current did not apply as regarded the length of the spark because until the discharge occurs there is no oscillation—it is a mere static charge. It is exactly like

the coats of a Leyden jar which are preparing to spark into one another and which do spark into one another when the difference of potential rises to a certain maximum and the area is broken down.

Concerning the duration of flashes, that again was a point on which much valuable work might be done by meteorologists and photographers. He had seen lightning flashes which certainly appeared to last two or three seconds. He could not imagine that it was one flash which was doing that; he thought it was a series of multiple flashes succeeding one another very rapidly. But whether they lasted long or not there was no necessary argument that they were not oscillatory. The fact that they deflect a compass needle does not prove anything about it, and does not prove anything concerning their duration either because a ballistic galvanometer is deflected by a momentary kick—a momentary blow given to a thing can deflect it, the blow having ceased long before the motion has ceased which it produced. But there is a difficulty which Mr. Preece did very well to advert to, and that is the magnetising power of a lightning flash. He thought that was the strongest point Mr. Preece had adduced. A flash magnetises steel bars, deranges the magnetism of a ship's compass, and conspicuously produces magnetic effects. Now an oscillating current ought not to produce these effects. An oscillating current with decaying amplitude is used by Professor Ewing to demagnetise steel, not to magnetise it. It ought not to magnetise, but it does magnetise them; therefore how can it be a current of this kind? But then the same difficulty would be felt with a Leyden jar discharge. The Leyden jar discharge is also oscillatory, certainly oscillatory because it has been seen to be spiral; the sparks have been analysed in a revolving mirror, and yet it magnetises steel needles when sent round them. He did not understand that point himself, but he hoped that Lord Rayleigh might say something about it. Mr. Preece was quite right in saying that the whole theory depends upon the oscillations. What he (Professor Lodge) had done, as far as the theory was concerned, was merely to call attention to these oscillations (which were well known in the case of Leyden jar discharges and of which the mathematics had been worked out) and to point out that they applied also to lightning which he thought had not been much noticed.

What the energy of a flash is he did not know. He wished there were some means of determining it; it would be very important to determine the energy of a flash. He would now say a word as to whether lightning was likely to be oscillatory or not—this question of what the resistance or friction has to do with the energy of the capacity which is discharged. The smaller the capacity the more likely it is to be oscillatory—the bigger the electro-magnetic inertia the more likely it is to be oscillatory. Now the capacity discharged in a flash is small. He said it was small for this reason, that the quantity of electricity discharged is not great. It was well known that the quantity of electricity concerned in a lightning flash was small. The quantity of electricity then existing in the portion of the cloud that is discharged is a small quantity, but the potential of it is enormous. It is able to spark 500 feet, possibly a mile—whatever it is able to spark it does spark. That meant an enormous potential. Now when they had a very small quantity raised to an enormous potential that meant that the capacity could not be great, capacity being the ratio of the two. There was no reason for supposing that the capacity of a condenser discharge in a lightning flash is anything bigger than a Leyden jar's, or in a micro-Farad, or things of that sort. He would mention as being perhaps interesting that the radiation of the waves produced by a micro-Farad condenser discharging from a coil of self-induction one secohm, as Professors Ayrton and Perry called it—he preferred to call it a 'quod'—the waves produced by that discharge—the ether waves, waves of light—if it is oscillatory will be 1,200 metres long. They had nothing like that capacity discharging in a Leyden jar, which has a capacity only, as he guessed it, of 10 metres electro-static units. Mr. Preece had promised to supply him with covered wire in order to repeat these experiments on the alternative path. He would have the greatest pleasure in taking advantage of it.

Then there was the theory of protection of area. Mr. Preece said, 'If it does not protect the area what is the good of it?' Well, but that was not an argument

proving that it did protect an area. He knew Mr. Preece's theory about the protection of areas because it had been published in the 'Phil. Mag.' The area, as Mr. Preece knew, was so extremely small that he thought they might almost give it to him without much argument.

Even then they would not be safe. Now why did he object to such a bit of protection as that? He objected to it mostly because he thought that areas of protection directed one's attention to side issues, to a thing which it is better not to think about because there is no certain area of protection as one could show in this way. Take another rod completely enclosed in this area of protection and bring it up near to the lightning-conductor. Now if area of protection has any meaning, that rod ought be protected; but he said that when a lightning flash—this was merely an assertion—strikes that conductor they would most likely, almost certainly, get a spark down the second rod, and it would take its share in operating to convey the current. Therefore that is not protected. If a man holds a lightning-conductor when a flash passes down it he will most likely be killed; and if it passed through—well, he did not know about gunpowder because gunpowder got blown about. It did not matter about the earth—about that being a good earth and this being a bad earth—still the same effect will occur; a spark is likely to occur if the distance be not too great. He said that that is so because he had made experiments in the laboratory after this fashion among others: he took a rod (which might be as thick as they pleased) a yard long and put it in circuit with a Leyden jar discharge, sending discharges through the rod. He then took a Wollaston platinum wire or any other wire, as fine as possible to make the contrast greater, and arranged it so as to make a kind of tapping circuit; if then the bottom end was arranged so as to be in contact with the rod and then let the top end be an eighth of an inch away or a sixteenth of an inch away, then they would have a splendid conductor, better than any lightning conductor ever was. They would have no trouble about earth; they would have close to it a little tapping circuit, the Wollaston wire which they could hardly see. It seemed absurd for any portion of the discharge to leave this conductor to jump across the sixteenth of an inch and to make for the little strip of wire. Nevertheless a portion of it did and from every spark that went to the conductor a side branch went to that little wire.

There was one point where Mr. Preece might have attacked him, but where he did not think that gentleman had made out the full strength of his case, namely, the question, What are the conditions of a flash? He (Professor Lodge) had assumed that a flash behaved like experiments in a laboratory, but it was a question whether a cloud discharge was of this kind. A cloud is not like a conductor; it consists of globules of water separated from one another by interspaces of air; it may be compared to a Spangle jar; when a Spangle jar discharges you have no guarantee that the whole of it discharges, it discharges in a slowish manner. It may be that there was with a cloud first a bit of a discharge and then another bit, and so on; so that there might be a kind of dribbling of the charge out of it, and they might therefore fail to get these oscillatory and sudden rushes. At the same time he did not think that they could always guarantee doing this, and it would not be safe in arranging for protectors to protect for only one case and that the easiest. They must provide for the possibility of a sudden and actual discharge. Still the conditions of actual lightning were to be met by observing lightning, and not by experiments in the laboratory. Thus they had the momentum of one spark exciting others; he was sure there were multiple flashes. There was a photograph which Mr. Abercromby had with him, and which he hoped would be shown to the meeting, where the flash is breaking the air down in all directions at once. It was most extraordinary the way in which there seemed to be a rod set up in the air so that one flash began and the whole thing smashed up in all directions. There was a point there which could only now just be called attention to, namely, the light of one spark assisting others to form. A spark of an induction coil here would be able to start the spark of another induction coil up in the gallery merely by its light; if it was closer it would do better but it would do it at a very considerable distance. When they came to consider the very bright light of a lightning flash

this effect must have very important consequences. He thought there was no doubt that once a flash occurs the light of it must make all conductors in the neighbourhood, all the air in the neighbourhood, very easily able to break down, and so may give rise to a multiplicity of flashes from all the neighbouring points. That was why he said areas of protection were misleading; if one flash caused a lot of others they had better not have the one if they could help it. Therefore he said, do not run up these great long rods to attract flashes near powder magazines or anywhere where it is dangerous, but try to avoid them if you can. If there must be a flash they must be very careful indeed to have all the other conductors arranged so that sparks along them do not matter, because if one occurred they were very likely to get the other.

The Hon. R. ABERCROMBY said he wished to be allowed to contribute to the discussion some facts which had been brought out by looking at about 90 photographs of lightning flashes in different parts of the world which had been collected by a Committee of the Royal Meteorological Society, of which he had acted as secretary. A few of the most remarkable of the photographs he had brought with him for the inspection of the meeting. In doing so he proposed to confine his remarks to such facts only as bore on the discussion they were having that morning, instead of ranging over the whole theory of lightning flashes.

The first point was, is there any evidence in the photographs of a duplication of flashes, that is, of one flash following rapidly after another? He thought the answer to that must be that there is no certain evidence. He had a very remarkable photograph with him, which might at first seem rather to negative that.

Here there was one very bright flash. In one place there were no less than three lines which were sorts of doubles of that bright line. In another part of the same picture they had a thin flash with another flash exactly parallel to it, only a little bit fainter. For reasons which it was difficult to give without a close inspection of the original picture, there was reason to suppose that that effect was due to a secondary reflection from the back of the glass. Although he was far from denying the alleged phenomenon, he thought they had often seen flashes come very nearly after each other, yet so far there is no photographic evidence of a flash coming exactly along the same path; but there is most decisive evidence of the tendency of flashes to be parallel to each other. He now exhibited a most magnificent photograph which had just been sent to the Committee from Massachusetts. In that instance the whole air is filled with threads of lightning coming down like the roots of a tree from the sky. He thought it was very much a question where the area of protection would be when the whole air seemed to be pouring lightning down upon you. There were other photographs in which appeared two or three flashes apparently following pretty much in the same path. Then, connected with this, there is the inveterate tendency of a lightning flash to ramify. Sometimes they got in a photograph a comparatively smooth line; at other times it was like that photograph which he had already shown the meeting. The main flash seems to throw out threads in every sort of direction. That would be observed in an influence machine; instead of a spark always coming from one to the other, they very often saw it begin to go off at right angles, and then jump away to the other.

Connected with that there was one thing of which he had not been able to find any notice in any of the discussions or publications on lightning-conductors, and that is, what is the effect of rain or cloud on the passage of electricity? All laboratory experiments are taken, of course, in dry air, but every experimenter knew that the dust in a laboratory has a very considerable effect on the discharge of static electricity. His impression was that when lightning comes down through rain or hail, or even through cloud, the continuity of what are called potential surfaces, and all that sort of thing, must be very much disturbed. The Committee of the Royal Meteorological Society had collected for this year of very frequent thunderstorms an enormous amount of material relating to them, including cases where much damage had been done to buildings. So much did he believe in the disturbance he had mentioned that when the Committee met again he should suggest to them to send out a circular with the object of finding out, if possible,

whether the buildings were struck during rain or when it was not raining. He was not quite sure but that they might learn something in that way.

There was another point which had been alluded to upon which photography he thought gave very conclusive evidence; that is, that lightning flashes are by no means as instantaneous as they are usually supposed to be. First of all, most people had seen lightning flashes which to their eyes appeared to last some time; but the evidence of the eyes in bright light is a little doubtful, as there are always subjective effects on the retina. They had a large number of photographs bearing upon this point, and he had brought with him a very good specimen. Lightning does not jump from the cloud to the air, but it goes meandering about in the air. It meanders about in the air without very much rhyme or reason, and flies about in a very eccentric manner. He thought it was perfectly certain that lightning, when it was tying knots like that, could not be going with anything which in ordinary parlance might be called an instantaneous speed. Of course there is no such thing really as instantaneity. Besides the ordinary flashes of lightning, some people had seen and everybody had read about what has been called a globular discharge of lightning, in which a ball of light, about the size of a cricket ball, goes dancing slowly down the street and eventually discharges. It is perfectly certain that between that very slow discharge and the quicker discharges which were ordinarily spoken of as flashes of lightning there must be intermediate rates of discharge. There was one point bearing upon this question of the non-instantaneity of a flash which had been adduced as evidence, but which the photographs in the possession of the Committee did not confirm. In fully half of the photographs the lightning does not cover the plate as a streak, but it is more or less of a banded nature, something like a ribbon. It had been suggested that this apparent motion that way might have been due to a shaking of the camera. There was evidence, —although he could not describe it verbally, it was easy to see it—to show that, and he could not think that that evidence of the slowness of flashes was not correct. Only yesterday their distinguished visitor, Dr. Janssen, made a suggestion to him which he thought furnished additional evidence of the fact. One of their most remarkable photographs, besides showing three white flashes on the picture, has a black flash; that was a very curious thing. They very early got the idea that that must be due to the inversion of the photograph, which sometimes took place from over-exposure. Photographers knew very well that, instead of white coming out as white, it came out black. It was a well-known peculiarity of plates and developers, and so on, but they were brought to a stand by the idea that this photograph was the only one instance that they had got, and if it should be over-exposure they would have a great many over-exposed. Dr. Janssen made to him the very valuable suggestion that that might be the evidence, not of a peculiarly bright flash which over-exposed the plate, but of a slow moving flash which moved so long that the plate was over-exposed. Of course it was impossible to say much from one case. He thought it was a remarkably brilliant idea, and he only brought it before them as a possible confirmation of what they were certain of from other things.

Then the only other point upon which he would like to speak was not connected with the photographs, but was a point upon which he would speak as a meteorologist, that was with reference to some remarks of Mr. Preece about the height of lightning clouds. He had no doubt that Mr. Preece might have seen it over a sufficient amount of country. The flashes might come from a cloud only 500 feet high, but that was a very low cloud, and in the majority of cases they certainly came from very much greater heights. In that one particularly that he had already alluded to, from the scale of the picture he was perfectly certain that the height of that cloud was considerably over 500 feet. At the same time he might mention that there was hardly a case of lightning much over 7,000 feet. When they got on the side of mountains much over that he would not like to say too precisely, but certainly a very moderate height, they always saw lightning below it. Electrical disturbance of this kind was confined certainly to the lower 10,000 feet of the atmosphere. In connection with the practical bearing of that he might mention that in Norway they had two kinds of thunderstorms. One occurred in

the summer, he believed, when the lightning clouds were high, and they got very little damage done; on the contrary, in winter time the thunderstorm clouds were very low, and the churches were very frequently struck. That, he thought, was all that he need say.

LORD RAYLEIGH said he had no special experience whatever of lightning-conductors, and could only speak from a general knowledge of electricity, no doubt to be applied in this case to very peculiar circumstances, so that everything that stood upon a merely *à priori* foundation should be put forward with very great diffidence. He must say, however, that Professor Lodge's experiments had seemed to him to be likely to have most important practical applications to lightning-conductors. He could not see how experiments dealing with the thing of all others most like lightning that could be produced in the laboratory could fail to have such an application. Professor Lodge asked one question and he thought mentioned his (Lord Rayleigh's) name in connection with it, as to how it could happen that an oscillatory electric current, that was, say, an alternate electric current beginning at a finite magnitude and gradually dying away, could produce magnetising effects such as they well knew that in some cases it did; and he instanced the very opposite behaviour, of slowly dying away alternating currents in the experiments of Professor Ewing and of others, in which such an arrangement was precisely the one adopted in order to get rid of even the last traces of magnetism. The question was a difficult one certainly, and he had intended in fact to make some experiments upon it himself; but he was inclined to think that the explanation might perhaps be sought in a case very much akin to the one with which they were now dealing, namely, that of the magnetic steel needle which was magnetised, say, by the discharge of a Leyden jar flowing through a spiral involving the needle. He said the needle itself was a conductor of finite dimensions, and that during the very rapid passage, and he had no doubt in some cases alternations of electric current through the spiral, there were induced in the magnet itself, in the steel needle itself, which ultimately became a magnet, circumferential currents, which circumferential currents would first, at any rate, protect the interior of the iron from the direct magnetising action of the enveloping helix. They must think not only of the action of the oscillating current in the helix upon the various parts of the steel needle, but also of the action of the currents developed in the steel needle itself. He believed it had been well ascertained that at different depths in such a steel needle they would very often find different degrees and even different directions of magnetisation. It seemed to him possibly that if that was thoroughly followed out they would be better able to understand what was certainly the fact, that a current that was certainly alternating and gradually dying away did nevertheless produce and leave behind it the effect of strong magnetisation.

There was only one other point that had occurred to him which it would be necessary to mention in connection with the development of atmospheric electricity, and he would like very much to hear any meteorologists present express their views upon it. He was reading only the other day a pamphlet by Professor Swankey, a man who had done very good work in other departments of science, in which he developed the theory that atmospheric electricity was due to the friction between water and ice. There was no doubt that many clouds (cirrous clouds he believed nearly always) were ice clouds, and not water clouds. Dr. Swankey's view was that at a certain level in the atmosphere ice clouds and water clouds could meet; and that under those circumstances this friction might occur; and his view was that the atmospheric electricity was the result of such friction. He quoted experiments by Faraday on the friction of ice and water, which had a positive result. But that was, perhaps, not the main question before them. He would rather hear from some more experienced and practical men, who had been at work on lightning-conductors especially, any instances of the kind that Professor Lodge asked for of actual failures of lightning-conductors. It seemed to him that it was only by actual experience of the lightning-conductors that the question could ever be finally settled. The laboratory experiments might be most important as suggestions, but he thought no one would wish finally to adopt any

system or to change any system of lightning protection without actual experience upon a large scale.

Sir WILLIAM THOMSON said: In respect to the very central difference between Mr. Oliver Lodge and Mr. Preece, he might say he thought Mr. Oliver Lodge was in the American stage with reference to judging the functions of inertia, and Mr. Preece rather in the English stage. They call it 'keeping our station' in England, but the Americans called it 'keep going ahead.' These are the two functions of inertia to prevent anything from getting into motion, and when in motion to keep it going; and both those functions were plain in this electrical influence. He could not but think that if Mr. Lodge continued his work he would find the explanation of the very great discovery that he has made, namely, that iron wire affords a better discharger, or an easier path in the circumstances Mr. Lodge had minutely defined, than does copper. He hoped Mr. Lodge would pursue the investigation, keeping the circumstances in all respects as similar as possible—comparing, for instance, a thin iron wire with a thin lead or brass wire of precisely the same ohmic conductivity. He knew that that gentleman had done a good deal already, but a good deal more might need to be done, and all that could be done by experiment could be done in a very easy investigation. The other point Dr. Oliver Lodge very importantly accentuated, namely, that the energy must be got quit of somehow and somewhere—it must be got quit of either in the conductor or elsewhere. If got quit of in the conductor, then there must be energy to melt the conductor, and it might be a positive advantage to have quasi-inertia to keep it oscillating for a time instead of volatilising the conductor in an instant. He did not hazard that in the slightest degree as an explanation, but it was certainly something that must be taken into account in connection with the experimental result which Mr. Lodge had put before them.

It was interesting to hear about the number of horses placed in a row, the first and last of the row being killed and the others not touched by a lightning discharge, which seemed to pass through them all. A very common lecture-room experiment was to give a Leyden jar shock to a hundred or two hundred students sitting on the benches, making them all join hands. He had no doubt that those students next to the ends of the line experienced the shock much more potently than those in the middle of the line. There was one very marked influence here, and that was want of perfect insulation; but there was another—self-induction. Self-induction was now in the air—they thought of nothing else in fact—and some of them thought of self-induction incessantly in these matters. He thought that the extent of self-induction might be tried, and that it would be a very interesting experiment. He thought they must also try this same experiment with as nearly as possible similar insulation with a number of people spreading out in a large circle. Then the self-induction would be much more influential in causing the discharge not to keep through the line of comparatively good conducting bodies. Take the case of persons ranged in a row taking an electrical shock; if the row is zigzag then self-induction will not have the same tendency to cause the lightning discharge to leave the line of the best conductors as it will have if the conducting bodies are placed in a wide circuit. Then he believed the imperfect insulation of standing on the floor would be much more potent, and he should expect that those who were in the middle of the row would experience a shock much less in the case of standing in a wide circle than in the case of standing on similarly good conducting material in a zigzag row. At all events that would be an experiment worth repeating.

Mr. Preece had spoken of the impossibility of conceiving of the enormous augmentation of potential in these actions. Take the word inertia which Mr. Preece used and the judiciousness of which he fully agreed with and apply it to the steam hammer and the hydraulic ram. They applied a comparatively gentle force to a steam hammer until it produced an exceedingly intense action at the blow. Take a hydraulic ram again, the well-known analogue for getting up a high potential by self-induction in an electric circuit, and he thought they would see that Professor Lodge's explanation of the phenomena he had brought before them was altogether valid and not very difficult to work out in detail.

Exceedingly interesting questions had been put and remarks made in respect to

the oscillatory discharge in ordinary lighting in respect to the duration of the discharge and in respect to the multiple flashes. He thought that Mr. Oliver Lodge had distinguished these more or less from one another. There might be a slow discharge. Mr. Abercromby had referred to a ball of lightning running about down the street, and so on. There was a curious description in Arago which Professor Tait credited (although he must say for himself that he scarcely credited it) so far as to quote in a lecture he gave at Glasgow some time ago, which described a ball of lightning as coming in at the window, running about amongst the people, and brushing up against their legs as if a kitten was about, and after that going out up the chimney. This slow discharge by ball lightning had been described very graphically by many people. He had never seen any description so minute as that of Arago's, which he must repeat he scarcely believed. He thought in respect to the duration that what Mr. Abercromby had called attention to was probably the true explanation. When people see a ball, as it were, passing along the floor, going up the wall and out at the window, he believed it was altogether a physiological affair. They had been looking in some direction or other when the flash came; at the instant that the flash came there was an intense action on the centre of the retina, especially if they chanced to see the flash in the sky; naturally after such a startling incident the eyes are moved and the person after seeing the flash looks about to see what has happened—looks on the floor, looks along the wall, looks up at the window, and a spot of light follows, so that he believed this marvellous ball of lightning could be seen by every person present going out of any window that he happened to look out of.

He thought Mr. Preece was perfectly right in speaking of the multiplicity of flashes of lightning. That gentleman gave some unmistakable experimental and observational evidence which agreed altogether with what he (Sir William Thomson) had noticed. The first time he distinctly remembered noticing it was in the year 1840, at Frankfort, where he had the pleasure of seeing a great many thunderstorms. He then remarked what he did not remember noting before, namely, triple and quadruple flashes frequently, but at such short intervals of time that one could not but think they were somehow connected, and yet at certainly long enough intervals of time to allow him quite distinctly to see that they were not one flash but several flashes. It was impressed upon him then, and had been since—because he had incessantly seen them since—that, as Mr. Abercromby had said, it did not appear to be a repeated repetition of flash along one and the same course, but a succession of connected flashes—a sort of breaking down all over the line—all over the place. One flash causes ever so many others: it is something like setting up a set of toy bricks or soldiers—tumble down one of them and there is a commotion all along the line, with a very sensible time interval. He thought something must be allowed for sound in this case. The light of one flash tends to produce another flash. If there is a flash just ready to take place between two knobs here, a flash there will cause it to pass, according to an experiment which Professor Schuster had given in his work, which had been a great deal referred to. As for the fact of lightning tending for the moment to make air more easily broken by the flash, it seemed that the very fine vibrations in light actually put the air into a more disruptive condition, or rather a condition that is more easily disruptive than air which is not agitated by light. That would not account for the time interval between the different flashes which were spoken of by Mr. Preece, and which he had himself repeatedly noticed. He thought there must be something in the velocity of sound—the velocity of the propagation of sound in the air. It seemed not improbable—he would not say improbable, for the first flash does produce certainly a tremendous disturbance in the air—a tremendous disruption of air probably causing a very perfect vacuum in the place of the flash and the shaking together of the air. He thought they could not account for it otherwise than by supposing a crack in the air suddenly filling up and producing an exceedingly sharp elastic disturbance. It is quite possible that that elastic disturbance coming at a time nearly equal to the ordinary velocity of sound to another place where they are in a state of high tension, ready to break down, causes it to break down. Thus it may be that one flash causes considerable numbers of others to spark at an interval of a quarter of a second, or

half a second, or one second from its initiation. This was a thing that might be experimented upon. Referring now to the photographs he observed that there was a great multiplicity of flashes shown in one of them. There were three flashes on one photograph, and one a great distance at the side—he supposed a mile or so at the side the distance probably would be. Query: Were they simultaneous? Perhaps Mr. Abercromby might say.

Mr. ABERCROMBY: We have no evidence; the photographs were sent to us without any particulars.

Sir WILLIAM THOMSON, continuing, said that the subject was always a most interesting one, but as it was now coming within the range of experimental investigation (which it could not be before the photographing of flashes of lightning was practised) he thought it would be worth while now to make experiments distinctly to ascertain whether such a group of flashes as that is or is not simultaneous.

There are some interesting points with regard to the magnetisation of steel needles by a helix in which there are electric oscillations which have been spoken of by Lord Rayleigh. If he remembered right Riess experimented on the subject some time prior to 1854. Riess (if he remembered right—and he was pretty sure he did remember right in this respect) found that when a Leyden jar was discharged through an insulated wire wound up in a helix in the ordinary way steel needles are sometimes magnetised in the direction that would be expected and sometimes in the contrary direction. He believed, as Lord Rayleigh had said, that experimenters have actually found differences of direction of magnetisation in different individuals of a group or bundle of steel wires thus actuated, thus exposed to this kind of magnetising action. If they had a very powerful current going in one direction, a current of half that strength going in the opposite direction, a current of a quarter the original strength going in the first direction, and so on, then they might expect the medium to be left magnetised by the current going in that one direction extending to the last time it had magnetising force enough to reverse the magnetism of the needle. So that he thought by experimenting upon Riess' old experiment with the same degree of electric magnetic inertia in different successive cases but different degrees of resistance, and therefore different rates of extinction of the oscillation, probably full explanation and investigation of them might be made, and they would understand how it might be magnetised in one direction and in the opposite direction. He was afraid that he was occupying too much time, but there was just what seemed to him rather an important point with reference to the protection of buildings. It was rather disturbing to find that a lightning-rod has so little protecting power as Professor Lodge had pointed out to have been proved by experiments. With reference to this distinction between iron and copper he would like to ask Mr. Preece whether he had experimental evidence of any superiority of copper. It was an exceedingly difficult question, but Mr. Preece had told them that his experience generally is that lightning-conductors are efficacious whether they are copper or iron conductors. There are certainly a great many iron conductors and he (Sir William Thomson) did not know of any experiment which proved that they were less efficient. On that he could not say anything certain at the present time. As Professor Lodge himself had pointed out, experiment after experiment must be gone through before they could say which it would be safer to recommend for lightning, whether iron or copper. There was one point upon which iron has greatly the advantage, that is, that it takes a great deal more heat to melt it. If they were to compare the cost of iron and copper they would have four or five times as great a mass of iron for a given sum. Take also the higher melting-point of iron and then they would see that for the same expense upon a lightning-conductor they would allow for the consumption of a great deal more energy within itself without destroying it by using iron than by using copper; but then the question of self-induction bearing on magnetisation must be considered before they could say for certain that in all circumstances an iron lightning-conductor is as safe as a copper one. He thought that the one moral, the one conclusion, which could be drawn from all this was, that a sheet-iron house with sheet-iron roof and sheet-iron walls and sheet-iron floor is the very safest place that we can possibly be in, or that gunpowder can possibly be in, in a

thunderstorm. Here he might say something which was perhaps absolutely wrong, but he would hazard it. The subject was full of pitfalls, and one could scarcely open one's mouth without putting one's foot in it in speaking of self-induction or magnetisation of iron and of discharge, but he would venture to do so. He would say that the magnetisability of the iron seems in this case rather to prevent the danger—rather to prevent the current coming into the inside than to facilitate its coming into the inside. He thought he might quite safely say this, that within an iron funnel—a long vertical iron funnel say—and within a copper vertical funnel the interior would be protected in the case of the iron funnel by the magnetic susceptibility of the iron; whereas in the interior of the copper funnel there would be no such protection, although in each case there would be a very potent protection from the conductivity of the metal. However, he thought that with what Dr. Lodge had put before them they knew quite enough about iron to say that an iron building will be as safe as safe can be—as safe as science can make it. He thought it was rather an important thing for powder magazines that the rule should be no lightning-conductors at all, but iron roof, iron walls, iron floor, wooden boards over the floor naturally to prevent people setting fire to the gun powder by walking over sheet iron, but a complete surrounding of iron; and then that might be placed on a dry granite rock; it might be placed on glass, it might be placed on anything they pleased, it might be placed over water—no matter what the surroundings are, the interior will be safe. He thought that was somewhat important practical conclusion that might safely be drawn from these electrical oscillations and mathematical calculations of which they had heard so much.

Professor ROWLAND, referring to Professor Lodge's experiment and the photographs exhibited by Mr. Abercromby, said the question seemed to be whether the experiment actually represented the case of the lightning. For himself he was very much disposed to think that it did not. In Professor Lodge's experiment the whole of the circuit between the condensers was a material of copper and iron whereas in the case of the lightning the greater portion of the flash was in the air and therefore it might be an entirely different phenomenon in the case of the lightning from what it was in the case of Professor Lodge's experiment. Furthermore he was not entirely disposed to think that the length of the spark was an index of the resistance of the conductor in that case, for the reason that they did not know what the length of the spark was when there was an oscillating electro-motive force acting on it. He was not disposed to say that the discharge would take place at the first moment; there might be considerable oscillation, and finally the air might break down. The oscillation might take place before the spark went, in which case the length of the spark might not be an index altogether of what they might call the temporary resistance of the conductor to the passage of the spark, and the presence of iron might change the time of the oscillation in some way, so that it might give a different length of spark in that case from what it did in the copper. But he thought the fact should be remembered that in the case of the lightning the greater portion of the spark was in the air which was a very bad conductor, and that therefore the discharge of the lightning might not be oscillatory, but might be of the nature of a swing, in which case a solid conductor or a conductor of copper would probably be worse than that of iron. With regard to the photographs he noticed many curious phenomena, which he thought should be guarded against. He was happy to say that the best one exhibited, which might form the text of his remarks on the rest of them, was an American photograph, in which case they had the whole plate exposed and the lightning in the centre of it. He did not suppose that all those flashes were taken at once, but that, as Sir William Thomson had remarked, the plate might have been exposed some time and have several discharges upon it. As he looked at that he noticed near the centre the lines of discharge were perfectly sharp. As he wandered off towards the edge he saw some phenomena which were very similar to those that he saw upon those other photographs, which therefore he would say were due to the astigmatism of the lens. For instance, some sparks were merely an astigmatic image of the true fact and in the corners and off on the side he saw sparks which were very similar.

M. DE FONVIELLE (who spoke in French) said he was sorry that he had the honour to be called upon to give his opinion on that occasion, as he arrived in the room late, but he would try to glance at some of the speeches that he had heard from so many distinguished electricians. Sir William Thomson said most eloquently that Mr. Preece was taking the English side of the question, and Mr. Lodge the American side, but he must say that Sir William Thomson had taken the French side and had proposed a revolutionary system which consisted in the building of iron houses. He took the liberty, though a Frenchman, to disagree with the great electrician and to stand with his friend Mr. Preece as an English Conservative of lightning-conductors. Lord Rayleigh said that mathematicians and physicists should unite together, but he supposed that he would agree with him in remarking that Mr. Preece was realising that alliance in a very remarkable manner, as on the one hand he was dealing with a large number of experiments and observations of nature, and on the other his application of statistics, or rather his calculation of probabilities, belonged to one of the highest branches of mathematics. The experiments done in laboratories differed from those which were presented by nature in regard to their size. On the previous day in that very hall his friend M. Janssen had proved by his observations on the action of oxygen on light that in many phenomena there was a coefficient behind varying according to the square or higher power. They might suppose that in electricity the law might relate accordingly to some unknown power, so they must wait for observations of natural phenomena from the clouds. They were so much more bound to wait because photography was now coming to their help, and it was impossible to say what were the powers he referred to until they had seen what photography could do. He would advise the meeting to delay its opinion until the time when his countrymen had erected in Paris the Eiffel Tower, which would be the most extraordinary lightning-conductor in existence, being a thousand feet high, and which would supply unprecedented means for observation and experiments. He must, moreover, state that Paris was practically free from calamities produced by lightning because they had a sufficient number of lightning-rods erected according to the principles so admirably advocated by Mr. Preece. That was strong evidence that Mr. Preece was in the right direction, altogether irrespective of any mathematical or physical question.

Professor GEORGE FORBES said:—Let them keep before their minds in this discussion what the question was which they wished to determine. The question had arisen from Mr. Lodge having come with those experiments to prove that the views of the Committee on Lightning-rods were erroneous. The Committee on Lightning-rods had come to a definite conclusion to make a recommendation that copper should be used for the lightning-rods, and Dr. Lodge had come to say that if iron was not better it certainly was as good; and that was the question which had to be decided. Now Professor Rowland had already said that it was not quite certain that the experiments which Dr. Lodge had brought forward were perfectly conclusive on this point. No one could fail to be enormously impressed with the beauty and the value of those experiments from a scientific point of view; but he thought that it was quite a fair position for Mr. Preece to take up to say that at present they had not proved the fact that the conclusions of the Committee on Lightning-rods ought to be given up. He would illustrate what he meant in this way. They had heard once of Professor Lodge's experiments very clearly put before them in which they had an alternative path either of copper or of iron. Previous to those experiments most persons would have expected that the copper would have been a better conductor for the alternative path. Professor Lodge assured them as the result of his experiments that copper was not the better but was probably the worse of the two.

Now he wished to show them the reason why he thought they were not fully able to accept that experiment as sufficing to abolish copper rods for their lightning-conductors. It was this. In the experiment Professor Lodge had used two condensers, and he had used a special case in which there were two sparks produced beside the alternative path. He asked Professor Lodge to tell them what was the result. He had doubtless tried the experiment when the experiment was

performed in a much smaller way, and more resembling the conditions which existed in an actual phenomenon. Suppose instead of using those two condensers they used the two poles of the Holtz machine, or instead of having two pairs of knobs suppose they used only one pair of knobs. They might connect the poles of the Holtz machine, if they pleased, with a large battery of Leyden jars, and they would get all the better effect. The arrangement then was that they got a spark between the two knobs of the Holtz machine. They connected that by an alternative path and then they tested to see at what distance it was just possible for a spark to take place. He wanted to ask Professor Lodge when that experiment was being performed whether an iron alternative path or a copper alternative path was the better. The circumstances seemed to him to more resemble the circumstances in nature than the arrangement which he had described in his experiment; and he thought the conclusion was that the copper alternative path was the better, which would be an argument in favour of Mr. Preece's view.

Sir JAMES DOUGLASS said the few remarks that he had to make upon this matter were in relation to his experience with a large number of conductors in exposed stations now extending over about forty years. He might say that his experience was comforting to the Committee. His experience was with lighthouse towers; and there they had been following out for nearly the last fifty years the advice of Faraday entirely. For protecting a lighthouse he advised them to start with the base of a metallic lantern. The conductors were of an inch and a half by three-quarters half round; that was to say, the half of an inch-and-a-half copper bar; they were carried down the interior of the tower, on the internal walls of the tower, with branches from all metal work in the tower. The earth was obtained by a copper plate 2 feet 6 inches square, buried at a distance of 15 feet from the tower and about 12 feet from the surface, generally securing damp contact. At exposed stations at sea the bar was carried down to about 8 or 10 feet below low-water spring tides so as to be always immersed in the wave. He might say that during forty years perhaps seven or eight accidents had occurred, but no accidents of a serious nature; and in all cases when an accident had occurred they had been able to discover that it was due to a defect in the conductor. Generally it had been found due to a mechanic who had been about the station who had disconnected the conductor and had not properly connected it again. Therefore those were points which he felt confident were to be got over by more rigid inspection, and more rigid inspection was now being carried out. He for one would feel that he would be perfectly safe in any tower where this system was carried out, and where the conductors were properly looked after. Having them carried down in the interior of the building they had every opportunity of inspecting them, and he rarely visited a lighthouse but what he inspected every connection up and down, and generally tested the conductor with a common linesman's instrument from top to bottom.

There was one practical point on the question of iron *versus* copper, and it was this, the rapid corrosion of iron compared with copper. It was quite possible with an iron conductor in an exposed station, where they were subject to such a corrosion, no matter what their sectional area might be, if they visited that station in the course of seven or eight years they would find very little of that conductor left. He had known bars of large diameter corroding at the most rapid rate possible in this country, and of course it was much more rapid in hotter climates. He only introduced that as a considerable fact of experience with conductors in exposed stations.

There was one point that he had omitted to mention, and it was comforting to Mr. Preece that during forty years where those conductors had been carried out on towers in contact with dwellings only one case of accident had occurred to surrounding dwellings, and there it was due to the imperfection of the conductor in the tower. The mischief was caused to the dwelling by the imperfection of the conductor in the tower; it was not a case of the dwelling being struck from the outside.

Mr. SYDNEY WALKER, speaking from the point of view of the practical engineer, said:—Upon the question of iron or copper for practical purposes, he should

certainly say that iron would not be as good as copper, because, as Sir James Douglass had pointed out, iron would not stand. It was not only a question of the weather, but at the top of a chimney—for instance, at the top of a factory chimney—the bricks are red-hot; and in the case of iron works and other places anybody who examined the top of an iron works chimney would see some material there, some chemical deposit from the chimney, and he did not think that any iron conductor could live in the face of that, otherwise he would say that there is no difference between one and the other.

Mr. BROWN (of Belfast) suggested that if one were to use a revolving camera successive flashes in the same path would be separated on the plate, and it would be easy to calculate the time interval, knowing the rate at which the camera was revolving. He had used a revolving camera himself for the purpose of registering, and he might say from his experience that it would be quite easy to determine the tenth of a second. In order to investigate the other question as to successive flashes in different paths, that could easily be done by setting up one stationary camera to photograph the thing in the ordinary way, having a secondary camera revolving on a vertical axis, and comparing the photographs.

Mr. SYMONS said he ought perhaps to offer some apology for speaking on this subject, but the fact was that it was a thing to which he had devoted his attention for considerably over thirty years. In fact, as far back as 1859 he was present at a discussion on lightning-conductors, the one at which Sir William Thomson made the very remark which had been referred to that day. He dared say Sir William would remember the remark on that occasion, that when he suggested to the Glasgow manufacturers to set up lightning-conductors they all said it was 'cheaper to insure.' Lord Rayleigh said it was desirable to get the evidence of practical men. He had nothing to do with the construction or the erection of lightning-conductors, but all his life it had been a hobby of his own to investigate every accident that he could possibly hear of involving damage by lightning; and in that way he had got, he supposed, experience which was certainly not theoretical, but it was possibly of some value. Then eventually, when it came to be a question of drawing up this code of lightning-conductors, he was one of the Committee, and they did him the honour of making him Secretary, and the consequence was he had had a great deal of evidence brought before him; and he must say that the impression left upon his mind as the result of the whole of his experience was precisely in accordance with that of Sir James Douglass, namely, that, as far as they could judge, if people would only put up conductors precisely in accordance with their rules, fulfilling all those conditions, those conductors were absolutely safe. He had not a shadow of hesitation in saying so. He admitted that accidents had happened now and then to buildings which had conductors, but a reasonable explanation of every one of those accidents to the best of his knowledge was forthcoming. They all knew how very much easier it was to produce destructive criticism than constructive criticism. Professor Lodge's experiments (and he yielded to no one in appreciation of him as an experimenter) were simply laboratory experiments after all, and it seemed to him that what they wanted was something on an infinitely larger scale. He was not going to suggest how they could make artificial lightning, so that they might deal with the actual thing itself, although he must say that the idea had often occurred to him that a great deal of information upon the subject could be obtained, if upon the summit of some of those hills which they knew were most frequently struck, a series of interrupted conductors were put up on tall masts where the lightning would presumably strike, and would strike of course without risk to human life, and they might thus learn a good deal more than they knew at the present time. He certainly did feel most desirous on the one hand that if possible a lightning-conductor should be cheapened and rendered more generally accessible; but on the other hand that they should not simply on the strength (as he said before) of those laboratory experiments allow to go forth from this great Association that there was any uncertainty in the protection of the public buildings throughout the country. It seemed to him that a very serious responsibility attached to those who would make a suggestion of that nature. They had experience, not only in this

1888.

country, but, as M. de Fonvielle had said, in France; they had it in Germany; they had it in Austria and in the United States on an enormous scale; and tens of thousands were erected and millions sterling had been invested in the subject, and he must say that it was with considerable hesitation that he would hear it go forth from that room that simply on the strength of some laboratory experiments all that had been done was to be regarded as almost worse than useless. The discussion had already gone on so long that he should be sorry to enter into many of the points upon which he had made some notes; but there were two or three upon which he should certainly like just very briefly indeed to say two or three words.

He had forgotten who it was; but one of the speakers made, he thought, very justifiable allusion to Arago's remarks about the ball of lightning rubbing against his trousers; but as to the existence of ball lightning, or some phenomenon of slow lightning, he had heard of it from so many hundreds of persons in all parts of the country and in all countries of the globe, irrespective of having on one or two occasions seen it himself, that he could not dispute its existence. As for understanding it, he did not. He remembered quite well the experiments that were made—he was not electrician enough to say whether they were correct or not—but experiments were made at one of the meetings of the Society of Telegraph Engineers by Mr. Varley in which he produced something closely analogous to the phenomenon of ball lightning. How far that was or was not the exact thing it was not for him to say.

Then with respect to iron conductors. First of all there was, as Sir James Douglass said, the question of oxidation. He should be told, 'Oh, it can be galvanised.' But he knew enough of galvanised iron to know that galvanised iron was not an everlasting material by any means. And then another thing was, as had been well pointed out, that the gases coming out from many of our factories were seriously injurious. With respect to the area of protection, he knew that there was a little bit of chaff about that diagram, but he did know also that he was within the mark in saying that hundreds of cases had been investigated and that there was not, as regards the area of protection laid down in the report of the Lightning-rod Conference, in the whole world more than two instances, and those were a little bit doubtful, in which anything had been struck within that area of protection. The attacks all round were alarming. One would be afraid to go to church in a thunder storm because the conductor on the top of the church would not protect you. Up to the present time there was not a single case of a church having been struck which was protected with a good and efficient conductor. Churches were struck every year. What happened? Sometimes, as one of their friends said, the bottom of the conductor was let into a paving stone. Away in South Wales, at the Cathedral of St. Asaph, they had a conductor laid into a pickle bottle. Of course if people went into that they would see that it was stupidity to allow a country blacksmith to put them up. There was such a thing as a properly made lightning-conductor. His friend Mr. Preece, in spite of all his attention (and he did work thoroughly hard upon that report) had not thoroughly mastered the report itself. The report suggested that what was called the upper terminal—that was the extreme top—should consist of a blunt point surrounded at about six inches below the top by a small ring from which very sharp needle-points should project. The idea of the Conference in designing that upper terminal was (he was afraid he did not use proper electrical language because, as he said before, he was not an electrician) that the acute points, the very sharp needle-points down below, were to disperse the electricity and act as a preventive; but if a disruptive discharge occurred, if the cloud came up so rapidly that the points could not get the potential down fast enough, and a disruptive discharge came upon the conductor, the absolute top of the conductor was nearly round. And the object of that was this, that if a disruptive discharge fell upon a sharp point it invariably melted it. Just going back to one point with respect to the small wires he felt quite aghast for this reason, that he had been in a dozen of houses which had been struck by lightning, and almost the first thing that was found was that the bells went wrong, and the fact was this, that the lightning as a rule got into the bell-wires; it dispersed them in dust, as a brown mark all round the walls of the room and every

wire was gone. If the old-fashioned conductors as thick as his fingers were to be replaced by something analogous to bell wires he wondered what was to happen after the first flash.

Mr. TRUEMAN WOOD wanted to say one word about two of the photographs. The so-called black flash, the dark flash, whatever that was, it certainly was not the result of over-exposure, as had been suggested, because the white flash, which was presumably on that theory less exposed, overrode the black one. Whereas, of course, if the black part was a part of the plate which had received most exposure, the black one would show over the white one. In that other photograph there was an exactly similar dark line which was evidently the result of reflection from the back of the lens, and therefore he thought there could not be the least doubt that this so-called dark flash was really the result of reflection from the other flashes.

The PRESIDENT: I think, gentlemen, we have now had a great deal of information brought before us, and in order to finish up I will ask in the first place Lord Rayleigh to make a short statement about the black flash, and then I will ask Mr. Lodge to give a reply, and then Mr. Preece will have the opportunity of finishing up with his remarks.

Lord RAYLEIGH said he would repeat the suggestion that Professor Stokes once made. He did not think it had ever appeared in print, and he was not quite sure whether he ought now to mention it, but he was encouraged by Sir William Thomson to do so. He thought there was no doubt, as Mr. Wood had said, that the appearance of the black flash did not suggest that over-exposure was the explanation. Professor Stokes' view was this, he thought that under the influence of a flash the atmospheric gases of oxygen and nitrogen were combined so as to produce considerable quantities of the oxides of nitrogen; that those oxides of nitrogen formed therefore along the line of the flash were highly opaque to the invisible rays at the upper limit of the spectrum to which most of the photographic action was due, and that then when another flash occurred, illuminating the background of the cloud to hide the place where the first flash had been, the mark of the first flash was depicted as a black line on account of its opacity to the general light of the background.

Professor OLIVER LODGE said so many things had been remarked and so much might be said even that had not been commented upon that one must exercise caution in what one mentions. He must, however, say a few words that had been suggested by the remarks of the various speakers. Mr. Walker and Mr. Symons and also Mr. Preece originally had spoken as if he (Professor Lodge) had especially attacked the report of the Lightning-rod Conference. That he had not done. He had made great use of the report of the Lightning-rod Conference; he thought that they had done a very valuable piece of work. They had collected together all manner of details of destructions and of failures of lightning-rods. The whole of the report was bristling with failures of lightning-rods, so that he was at a loss to understand—no, he did understand how it is. They said that a 'properly constructed' lightning-rod never fails, because whenever a thing fails they always say there is something the matter with it. They generally say bad earth; but why a thing ought to have such an extraordinarily good earth he never could tell. What is the difference between one end of the conductor and the other? They stuck three points at this end and they wanted a lot of rods at that end. Suppose it was reversed; why they would have the rods in the sky and the points down below. Why should one end have to be treated so very carefully and the other end be left to itself? As far as protection is concerned three points at the top and the three points at the bottom ought to do equally well. Of course it might be inconvenient to have the ground ploughed up, and you might have the ground and water-pipes broken if you have not good earth. He said they ought to have a good deep earth. Flashes ought not to spit off from the conductor to the gas apparatus, nor to explode gunpowder, nor run along gas-pipes and play the fool dancing along any part above the earth. It did not do that because it met with obstruction and impedance—he did not care what they call it, a spurious resistance—they might use the word resistance if they liked, but it was not what they ordinarily called resistance, it was like inertia. It was like having to move.

a great weight ; there is no resistance to its motion, you may knock it about with a hammer and expect it to fly to the other end of the room, but it does not move, although you may knock the hammer to pieces and do a great deal of damage to it. That was the kind of obstruction that was met with in the lightning-conductor. As regarded the failures of properly constructed lightning-conductors he wanted to know from Mr. Symons (there would be plenty of opportunities for continuing this discussion in print) why had M. Melsen's Hôtel de Ville at Brussels got set on fire by a lightning flash? because if anything is well protected and admirably and thoroughly protected according to orthodox principles that building was safe. He (Professor Lodge) thought it was protected too. When he spoke of its not being completely safe he did not mean, and he never thought of meaning, that lightning-conductors are of no use. They are of very much use, but they may occasionally and he believed do occasionally fail. M. de Fonvielle spoke of the great experience Mr. Preece had had, and also of the great experience that they had had in Paris with all manner of conductors ; for lightning-posts and things like that they did not fail much. But then a lightning-post and an obelisk and a lighthouse even are the easiest possible things to protect ; there is just the one column and if you stick one protector down there is not much chance of its splitting, or of its doing much damage to anything else. In the Monument of London the handrail of the staircase, he believed, is the lightning-conductor ; he did not know what it would feel like when it was struck ; he dared say it had been struck, probably in the night when nobody was there, but he believed it had not been damaged in the least bit. It was not much use to protect powder magazines and houses where there is escaping gas. If the lightning flash went down near a leaden gas-pipe it would very likely fuse the pipe, and they would have the house burnt down. They might not know that the house had been struck, but they would wake up in the morning and find themselves burnt.

Professor Forbes asked him to say why he did not use one pair of knobs instead of two pairs of knobs to try the experiment with. If Professor Forbes tried the one pair of knobs he would find that he could not perform the experiment at all ; there must be two pairs of knobs somewhere.

With these oscillating currents, which are of extremely great frequency (there are something like a million a second), it is only the outer surface that is obstructed. It is due to the space surrounding the conductor, and it is not due to the material of the conductor. It is the tube of the conductor that flies ; therefore the conductor does not get magnetised at all, whether iron or copper ; the thing does not care about its permeability, its magnetic properties, or its conductivity much. The current is very great even from an ordinary Leyden jar ; the current produced when discharging is about 3,000 ampères. The current in a lightning flash is, no doubt, enormous ; he should think a million ampères for the time it lasts. That it is very great is shown by the heating powers and the destructive powers that it has, only the duration is so extremely small. Hence it is that the impedance is so very great, because there was a certain amount of ohms, and then there was a tremendous current, and so they got the tremendous difference of potential at the end and the liability to spit off. Seeing that only the outer surface conducts, what is the good of the inside of the rod? It may have to conduct the heat away, and so prevent the heating, or it may not have time to do that ; probably there is no particular good in it, but if they were going to have a tube they had better have a flat tube, and it was also better to have a strand of separated wires or have a series of wires about the size of telegraph wires. Mr. Preece knew very well that the iron lightning-conductors on the telegraph posts protected them, and a house would be protected in a similar way, and chiefly by putting a great number of common galvanised wires up. That was his view, but it was not authoritative. If what he said was authoritative, and would be sent forth as a statement made in that room, of course he would hold his tongue ; but of course one simply said that which one thinks at the time. It is found that all the failures of lightning-conductors are due to the spitting off, are due to this high potential, are due to the impedance of it, the obstruction of it—to the fact that it does not conduct so easily as they would expect it to do, and not due to the melting of it. Mr. Symons, in his Lightning-

rod Conference Report, gives in Appendix K a list of conductors which had been melted by the flash, and he apologises for the shortness of the list. No apology was necessary, for they very seldom got melted, and if they were to analyse those Mr. Symons gave they would find in every case that the upper terminals had been melted (as they might have expected) and not the full length of the conductor. There was only one case, and that was of a bell-wire. When bell-wires were used then they were melted, but he did not want wires to be put up which were of the thickness of bell-wires.

Iron buildings, as Sir William Thomson had said, are practically safe for powder magazines. They are the safest things that could be made, but even with them some little care must be taken; the iron must be in absolutely good connection all through. If there is a gap left anywhere there may be a spark at that gap. When an iron building is struck they might have the electricity surging about in all directions, and they might get sparks in the most unexpected places and for the most apparently ridiculous reason. The gap might be only half an inch long or a quarter of an inch long, but that would be quite sufficient to light the gas and do all the damage. It was that danger in the case of gas and in powder magazines of having gaps only a quarter of an inch long, and they might get them where they least expected them.

As regards the possible effect of sound waves he would just call attention to one little experiment which was not his at all—it was first made by Dr. Guthrie, but it had been called attention to at the Physical Society afresh and independently by Mr. Cooke, he thought. They took a discharging Leyden jar, which, as he had often said, gives ether waves of a calculable length. Now this modification of the experiment had been made by his friend Mr. Chattock. That gentleman took a little tube like a resonant tube, sprinkled powder in it, and when the spark crossed near the mouth of that tube it was drawn into it like the ripples in the sand, indicating that a longitudinal wave had done that. These longitudinal waves were extremely short, about a millimetre in length. Sound waves are practically one-millionth of a light wave. That was evidence of the oscillation. The spark is subject to longitudinal waves due to vibration sound waves, about a millimetre long, which throw the sand into ripples. It may be those longitudinal sound waves of which Sir William Thomson spoke which may from some action or other precipitate a response in the neighbourhood, though no doubt there are other causes too.

Mr. PREECE said he would not occupy their time much, because there would be other occasions when the points at difference between them would be argued. He might say they had dwindled down to a very small thing indeed. As regarded the question of iron and copper, in answer to Sir William Thomson, most, in fact all, of those lightning-protectors of which he had actual experience were of iron, and he had always been, as most of them knew who had read the reports he had written, a great advocate of iron. He thought the use of copper to the extent to which it was used introduced a needless expense into the erection of lightning-protectors. His own impression was that every private house could be thoroughly protected, according to the recommendations of this Lightning-rod Conference, for at most a pound. Anybody could buy a coil of stranded iron rope, and if they took an iron rope about a quarter of an inch in diameter, with the finial Mr. Symons had referred to, he believed that they could safely protect their houses with lightning-protectors for a few shillings, instead of now, where copper was employed, indulging in the expenditure of a few pounds.

The PRESIDENT said he was sure they had all heard with very great pleasure this discussion that had taken place, and it was with very great diffidence indeed that he felt called upon by his position as President rather than by any desire to do so to say a few words in summing up what seemed to him the result of the discussion. He was glad to say that he had had no experience of lightning. It was not an agreeable thing to have anything to do with. However it was most closely allied—there was no doubt about it—to static electricity, which he had heretofore looked upon as one of the most beautiful but useless adaptations of nature, and he hoped now that these experiments with what had been called static electricity would gain fresh interest from the practical applications that

might be likely to be derived from it. It was very important to observe that there were a number of experiments that had taken place, especially in connection with some tramway lines, with telegraph instruments and with telephones with effects that had taken place at terminal stations at considerable distances from the lightning which required to be investigated, and about which they knew very little, and which had not been considered very much.

Mr. PREECE said he meant to point out what Professor Fitzgerald was now saying, that they had had experience in their telephone exchanges and in their electric light installations where there was a mere metallic conductor, and their experience was that in practice it was exactly what Professor Fitzgerald now referred to, and it was a most interesting point.

The PRESIDENT said he thought they were all very much obliged to Professor Lodge for his experiment, because heretofore he thought there had been little or no experimental observation of this particular point, and it was a very important thing to them, especially if telephones were likely to become of use on a large scale, that during thunder storms, if they could possibly do it, they should protect people from injurious effects owing to the presence of the thunder storm, perhaps at a considerable distance from the person that was using the telephone. It was very analogous, it seemed to him, to Professor Lodge's experiments, and they were very much to the point in that connection. He was inclined to think that the experiment that Professor Lodge had performed was not exactly analogous and in many ways was not at all analogous to a lightning flash. Mr. Preece had called attention to a fact that a lightning flash was very much more like a discharge between the plates of a condenser, much more like the breaking down of the insulation in a Leyden jar when it burst through the glass. Mr. Lodge's experiments had not been on the effect of putting a point upon one of the plates of the air-condenser, and if he did make some experiments on it, he thought it would be found there would be a considerable diminution of sparks.

Professor LODGE: If you have read my paper you will find those experiments have been made too.

The PRESIDENT said he was afraid he had not studied the thing completely, but the experiments that were alluded to that day were not exactly analogous.

Professor LODGE: No.

The PRESIDENT, continuing, said he thought it would have been well if they had been told of experiments which were exactly analogous. There was a question with respect to the alternation of currents, and he would call Mr. Preece's attention to this, that even though there might not be millions of alternations per second a great many of the effects of the alternating current would be produced by an extremely sudden current of very short duration. A great many of them would be produced by a single sudden discharge of a millionth of a second. It might be that some of them would not, but a great number of the effects would be, and he thought also a great number of effects would be produced similar to those that Professor Hertz had observed, where at a distance from a spark he had observed electro-magnetic effects. Those might also cause electro-magnetic effects in the inside of the house, due to a spark of electricity occurring outside the house. He would like to make one other remark. The globular lightning might possibly be due to the dissociation of the molecules of the air, if there be a region of the air in which there were atoms going about by themselves, combining among themselves and producing an illuminating part of the air, the original dissociation of the atoms having been produced by some electrical action.

In conclusion, he thought the principal thing for them to pay attention to was that 'prevention is better than cure.' As M. de Fonvielle had reminded them, there was very little doubt but that the presence of a very considerable number of lightning-conductors undoubtedly affords a great deal of protection to the area within which they exist. M. de Fonvielle had remarked that in the city of Paris they hardly ever had any accidents from lightning. So that it is very desirable that if possible the whole country should be covered with lightning-conductors in order that they might have as many points as possible, and thus, as far as they could, prevent the occurrence of lightning. There was no doubt that when a flash

occurred it was extremely disagreeable, and that they had better take example by the old rule that 'absence of body' is better than 'presence of mind' and avoid being near a flash if they could.

He did not think there was any doubt, quite independent of any experiments of Mr. Lodge's, that, as a matter of experience, lightning-conductors have protected buildings, whatever the explanation of it is, nor that there was any doubt that we have been right on the whole in our methods of erecting conductors. Perhaps there are improvements possible; perhaps we might be able to protect ourselves from those unfortunate discharges that occur in telephones, and so forth; but, as a whole, lightning-conductors have been a great protection to mankind from danger by lightning. That is undoubtedly the result of our experience.

2. *On the Burning by Lightning of a Magnet on a Generating Dynamo at the Waterfall on the Bush River, County Antrim, belonging to the Giant's Causeway and Portrush Electric Railway and Tramway Company.* By ANTHONY TRAILL, LL.D., M.D.

I happened last month to be travelling on this line in a thunderstorm. The electric car was going well, at about twelve miles an hour, when I observed that the main power of the current suddenly left us, and we were with difficulty able, at a very reduced speed, to finish our journey. On arriving at Bushmills I drove up to the waterfall, on the river Bush, where the electric station is situated, and there found that one of the magnets of the five-ton dynamo (Elwell-Parker) had become short-circuited, the series wire and shunt wire having been fused into each other, and the thick ply of all insulating material burnt up. The turbine-driver stated that just at the moment of a heavy thunderclap there was a tremendous flash of lightning all through the room, and the rupture of the magnet took place at that instant.

On a former occasion during a thunderstorm there was great consternation both in the generating-room, where there were great flashes on the brushes of the dynamo which were burned, and on the car, which was travelling on the line, where the lightning seemed to play all round the car for some moments, and especially to flash on the brushes and about the starting commutator which puts on or cuts off the current from the car. The driver of the car was so alarmed as to stop the car and jump off, but no injury was done to the car or to the motor apparatus in it.

Query: Should lightning-conductors be placed at the generating-station and along the main line?

3. *Analyse chronométrique des Phénomènes électriques lumineux.*

Par Dr. J. JANSSEN.

Le principe du revolver photographique proposé par l'auteur en 1874 à propos du Passage de Vénus, et qui a été appliqué depuis si heureusement par M. Marey à l'analyse des mouvements du vol des oiseaux, peut donner également la solution de divers problèmes de physique et de mécanique, et notamment celui où l'on se propose d'analyser les circonstances de la propagation des phénomènes lumineux dans les étincelles électriques, les décharges, la foudre, etc.

L'appareil consiste en une chambre photographique portant deux objectifs de même ouverture et foyer. L'un des objectifs donne les images sur un disque animé d'un mouvement de rotation rapide et portant une pellicule photographique sensible. L'autre objectif donne les images sur une pellicule semblable mais fixe.

Quand l'appareil est en mouvement on en excite l'étincelle, ou bien si les étincelles se succèdent d'elles-mêmes on découvre un instant les objectifs.

Deux images se forment ainsi, l'une sur le disque fixe, et celle-ci est l'image normale, tandis que celle du disque mobile sera plus ou moins déformée si le phénomène ne s'est pas produit assez instantanément pour ne pas être influencé par le mouvement.

La comparaison de cette dernière image avec l'image normale conduira à reconnaître et à mesurer le temps écoulé pendant la production successive des diverses parties de l'étincelle.

On n'a exécuté encore que quelques expériences. Elles ont été faites sur des étincelles produites avec une bobine de Rhumkorff; et déjà on a pu constater que dans la production des étincelles à plusieurs branches partant d'un même pôle la production des diverses branches n'est pas simultanée mais successive.

Pour une même étincelle même la manifestation du phénomène lumineux donne lieu à des circonstances singulières sur lesquelles nous aurons à revenir.

Ces expériences seront poursuivies. Elles seront appliquées notamment à l'étude des phénomènes de la foudre.

4. *Report of the Committee for constructing and issuing Practical Standards for use in Electrical Measurements.*—See Reports, p. 55.

5. *On Standards of Electrical Resistance.* By R. T. GLAZEBROOK, F.R.S.

6. *On the C.G.S. Units of Measurement.* By W. H. PREECE, F.R.S.

It is suggested that the unit of work equivalent to 10^7 ergs be called the *Joule*, as proposed by Sir William Siemens. We should then have these relations:—

One joule = 10^7 ergs = .24 calorie (gramme-water degree).

One watt = one joule per second = .24 calorie per second.

One calorie = 4.2 joules = 42000000 ergs.

One British thermal unit (pound-water degree Fahr.) = 1058 joules = 252 calories.

The inconvenience of making the volt 10^8 units instead of 10^9 C.G.S. units, the very rough approximation of the legal ohm, and the necessity for some unit magnetic field are considered, and it is recommended that the standard of pure copper should be redetermined, for Matthiessen's standard is known to be wrong.

7. *Electrometric Determination of 'v.'*

By Professors Sir W. THOMSON, F.R.S., AYRTON, F.R.S., and PERRY, F.R.S.

WEDNESDAY, SEPTEMBER 12.

The following Reports and Papers were read:—

1. *Report of the Committee for considering the desirability of introducing a Uniform Nomenclature for the Fundamental Units of Mechanics.*—See Reports, p. 27.

2. *Second Report on our Experimental Knowledge of the Properties of Matter.* By P. T. MAIN, M.A.—See Reports, p. 465.

3. *On the Mechanical Arrangements of the Analytical Engine of the late Charles Babbage, F.R.S.* By Major-General H. P. BABBAGE.

The object of this paper is to give some idea of the mechanical contrivances employed to govern and control the analytical engine of Charles Babbage. It is scarcely possible to give in a short space a full abstract of what is already very condensed. Those who desire further information are referred to a volume of

about 400 pages now in the press at Messrs. Clowes & Sons', Ltd., containing nearly all that has been published relating to the calculating machines of Charles Babbage.

The paper sketches the origin of the engine in 1833-4 and describes the chief means employed to direct it. 1st. The cards which have been already more or less described. 2nd. The principle of 'chain,' by which any possible contingency among many may be provided for. There is a movable block for each event anticipated, which on the occurrence of the event is moved into a certain position; a lever or arm is made to act, so that when the movable block is in that position it is moved and passes on the motion to something else, effecting whatever change may be desired in the mechanism. If the block is not in that position, the lever moves in vain. This arrangement is applicable to one or to many events. The shape of the block may be varied to suit different purposes. This principle is used to put various parts of the engine into and out of gear automatically. It is also used in anticipating carriage, which is described at some length, showing how by the use of 'chain' every possible case of carriage in n figures may be mastered and the whole effected simultaneously, the mechanism indeed presenting to the eye a sort of picture of each combination as it occurs. A double camb is explained, which is extensively used for producing intermittent motion required at fixed times.

The frequent use of counting apparatus of sorts for recording and regulating the various trains of motion is mentioned, and the advisability of making these trains as short as possible and taking a fresh start from the motive power is urged. Various other details are more or less alluded to or discussed.

The notations and drawings (of which there is a full list in the forthcoming volume) are mentioned, and the system of 'mechanical notation' used by the inventor (see Proceedings of B. A. for 1855 at Glasgow) is mentioned; an instance of its practical utility is given, and its being taught in art and technical schools is recommended.

As regards the report of the Committee presented to the B. A. in 1878, it is urged that the powers of the analytical engine are not limited to the production of a 'single numerical result,' but can follow the mathematician wherever he can point the way, and that its processes (including division) are not tentative except so far as the mathematician makes them. Some further objections are made to certain points in the report, which, considering the improbability of the engine ever being constructed, may be here passed over. It is admitted that the scope and powers of the design may be very considerably restricted, with the result of leaving a machine which would still be excessively useful and which would inevitably lead the way to further progress.

It may here be stated that a piece of machinery working to 29 places of figures, and embodying the anticipating carriage, was shown during the meeting to several who desired to see it. The anticipating carriage works perfectly, and was much admired by those who saw it.

4. *On a Modification of Maxwell's Equations of Electromagnetic Waves.*
By Professor H. A. ROWLAND.

5. *On a Photographic Image of an Electric Arc Lamp, probably due to Phosphorescence in the Eye, and on some Photographs of an Eclipse of the Moon.* By FRIESE GREENE.

The eye was exposed to a 2,000 candle lamp, the current was switched off, and a sensitive plate was immediately held before the eye. Some of the plates afterwards showed a minute picture of the glowing carbons.

Photographs of the moon were also exhibited which had been taken by what was practically a Newtonian telescope without a lens.

6. *On the Errors of the Argument of Statistical Tables.*

By JOSEPH KLEIBER.

The object of the paper is to show that statistical tables and generally tables giving the result of observations on two covariable quantities are *not invertible*, the values of the function not corresponding exactly to the values of the argument as indicated in the table. The correction to be applied to the argument for the inversion of the table may be calculated by very simple formulæ. If we have a table giving a series of values of y for equidistant values of x , and we take for unity the distance between two consecutive values of x , then the true value of an argument x_i is represented by the integral

$$\int_{x_i - \frac{1}{2}}^{x_i + \frac{1}{2}} xf(x)dx \quad . \quad . \quad . \quad . \quad (1)$$

$f(x)$ being the probability curve of x , which may be approximately found by considering the distribution of the number of cases, when x had given values x_1, x_2, \dots . If we have, for instance, n_i cases of x being equal to x_i , and the total number of observations = n , then

$$n_i = n \int_{x_i - \frac{1}{2}}^{x_i + \frac{1}{2}} f(x)dx \quad . \quad . \quad . \quad . \quad (2)$$

From a series of values of n a parabolical expression for $f(x)$ may be calculated by means of the formula (2), and this expression being substituted in (1) gives with sufficient accuracy the required correction.

Ex.—In the simplest case of three observations being given, corresponding to the arguments $y = -1, 0, 1$, and the number of cases of $x = -1, 0, 1$, being respectively n_{-1}, n_0, n_1 , we find for the correction of the value $x = 0$ the formulæ

$$\frac{1n_1 - n_{-1}}{8n_1 + n_0 + n_{-1}}$$

if we have for $f(x)$ a linear expression, and

$$\frac{1}{24} \frac{n_1 - n_{-1}}{n_0}$$

if $f(x)$ is represented by a parabola of the second order; and similar formulæ may be found for higher orders of parabolæ and larger numbers of arguments. The paper will be prepared for publication in the 'Philosophical Magazine.' Examples of application to meteorological tables will be given in the 'Meteorologische Zeitschrift.'

7. *On Geometry of Four Dimensions.* By EDWARD T. DIXON.

In this paper the author begins by pointing out that the principles of geometry of four or any number of dimensions might be worked out analytically, even if they could not be interpreted. He then proceeded to explain how it was possible either to conceive a fourth independent direction or to graphically interpret geometry of four dimensions without this conception by regarding the density of a solid as a geometrical dimension analogous to length. Thus mass became a geometrical dimension as well as length, area, and volume, and any equation in four variables might be graphically represented by a solid body of varying density.

8. *A Suggestion from the Bologna Academy of Science towards an agreement on the Initial Meridian for the Universal Hour.* By Dr. CÆS. TONDINI DE QUARENGHI.

In a letter dated June 18, 1879, to the Secretary of State for the Colonies, and relating to the choice of the initial meridian for the universal hour, Sir G. B.

Airy, Astronomer Royal of Greenwich said: 'Nearly all navigation is based on the Nautical Almanack, which is based on Greenwich observations and referred to Greenwich meridian. . . . But I, as Superintendent of the Greenwich Observatory, entirely repudiate the idea of founding any claim on this.' Unfortunately this advice has not been listened to, and though, to use Dr. Struve's expression in his Report on the Washington Conference of 1884, 'a law relative to the unification of time notation is of less relative importance to the navigator,' the preference there given to Greenwich was almost exclusively based on the argument disclaimed by Sir G. B. Airy.

A comparison more or less derogatory to the Paris Observatory was also, unfortunately, transparent; which, of course, could not fail to be unfavourably resented. The result was that France, which had propounded the principle of neutrality or internationality, abstained from voting. The same did Brazil. Now, as it has been there remarked, any resolution passed without the consent of France would not answer the scope of the Conference.

That things are now no more advanced than before the Washington Conference is proved by the very message of the President of the United States to the Congress, dated January 9, 1888, recommending the Government 'to take action to *approve* the resolutions passed in 1884 and to invite the Powers to accede to them.' They are, consequently, not approved yet, nor have the Powers acceded yet to them.

Moreover, the delegates of the 26 Powers there represented declared, from the very beginning, that their presence there was only *ad referendum*, and could not in any way bind their respective Governments. What *these* consequently really think on the subject is unknown, and they are still at liberty of giving or refusing their adhesion. Other Governments not represented at Washington, say Roumania and China, may claim a right to give an opinion, which may equally result either in diminishing or increasing the opposition.

On the other hand, the urgency of the unification of time is every day more keenly felt, and Mr. Sandford Fleming, its fervent promoter, can now safely rely on general opinion. 'All sciences,' says again Dr. Struve, 'are in common interested in it,' and he expresses even the hope that 'it might be arranged to come to pass in 1890.'

Finally the simultaneous use of more than one initial meridian is acknowledged not to be without some advantage for science, as stated in M. Caspari's Report for the French 'Commission de l'Unification des longitudes et des heures' (August 1884). It cannot, for instance, be denied that they offer a means of controlling and securing the correctness of 'Ephemerides.'

For all these reasons, and to prevent the unification of time being indefinitely postponed for want of agreement on the initial meridian, the Bologna Academy of Science submits to the British Association the following suggestion contained in a Note of theirs recently addressed to all scientific bodies represented at the festivals of the eighth centenary of the Bologna University in June last, viz.—

'That, navigators and astronomers being at liberty to go on using their own initial meridians, another truly international meridian be chosen for all other purposes for which the unification of time is required. That, moreover, since the Jerusalem meridian has already the suffrages of scientific authorities, its appropriateness to serve as the universal initial meridian be seriously taken into consideration.'

SECTION B.—CHEMICAL SCIENCE.

PRESIDENT OF THE SECTION—Professor W. A. TILDEN, D.Sc., F.R.S., F.C.S.

THURSDAY, SEPTEMBER 6.

The PRESIDENT delivered the following Address:—

A PART of the duty which devolves upon the President of a Section of the British Association consists in delivering an address, and the knowledge that a pretty full liberty of choice is permitted in regard to the selection of a subject is the only source of comfort which serves to alleviate the onerous nature of the task.

It seemed to me that the time is gone by when an attempt to review progress over the whole field of chemical science is likely to be useful or even possible, and an account of what is being done within the narrow limits of those parts of the science to which I have been able to give special attention would be ill-adapted to the character of a speech addressed to the members of the Section collectively. The fact that at the last meeting of the Association a Committee was appointed to inquire into the methods at present adopted for teaching chemistry suggested that, as I had not been able to accept an invitation to join this Committee, I might make use of this opportunity for contributing to the discussion. The first report of the Committee will be received with much interest by the Section. As might be expected, it embodies the expression of many varieties of opinion.

The existence of chemistry as a department of science not merely requiring the observation of facts that are to be made useful, but seeking in the accumulated stores of observation to discover law, is a thing of comparatively recent growth. How chemistry arose out of alchemy I need not remind you, but the connection between the study of chemistry and that of medicine, and the maintenance of this connection down to even the present generation, is illustrated by the fact that a large number of men who have become eminent as chemists began their career in the surgery or the pharmacy. Black, Davy, Berzelius, Wollaston, Wöhler, Wurtz, Andrews, and W. A. Miller began by the study of medicine, whilst Scheele, H. Rose, and the great names of Liebig and Dumas are to be found in the long roll of those who received their earliest notions of chemistry in the pharmaceutical laboratory. Chemistry has been gradually emancipated from these associations with enormous advantage to both sides. So long as technical purposes alone were held in view a scientific chemistry could not exist, but no sooner did the study take an independent form and direction than multitudes of useful applications of the facts discovered became apparent.

It is only within a comparatively few years, however, that universities, in this country at least, have ceased to deal with chemistry as a kind of poor relation or humble follower of medicine, and have permitted her to emerge from the cellars of a museum or school of anatomy and have given her a commodious dwelling in the fair light of day.

In the old time such instruction in chemistry as was given in the universities and mining or technical schools seems to have taken the form of lectures read by the professor, and access to a laboratory for practical manipulation seems to have been a high privilege accorded only under exceptional circumstances to the few. We are told, for example, that when Liebig went to Paris in 1823 he applied to

Gay-Lussac for practical instruction at first without success, and that admission to the laboratory of the *École Polytechnique* was ultimately granted him only through the intervention of Von Humboldt.

In a great many cases the student of chemistry must have been almost entirely dependent upon private study, though books were scarce and materials more costly than now. Davy, for example, seems to have had no instruction whatever previous to his appointment as assistant to Dr. Beddoes at the Pneumatic Institute at Bristol.

Doubtless, therefore, the recollection of his own early difficulties when seeking instruction contributed largely to influence Liebig in the establishment of the laboratory in the University of Giessen, and in the adoption of the principles which guided his teaching there. For the first time in the history of chemistry students met not merely to listen to the discourse of a professor concerning his own experiments and conclusions, but to examine for themselves the basis of the theories taught, to learn the processes of analysis, and by independent investigation to extend the boundaries of existing knowledge.

The fame of the new school spread fast and far, and soon men from every part of the civilised world assembled to share in the advantages offered. The influence of the new method can be estimated when we reflect that nearly all the now passing generation of chemists in England and America obtained the greater part of their training in Liebig's laboratory; and as a large number of them have been teachers, it may be assumed that they transplanted into their own countries the methods they had learnt from the great German master.

It was not till 1846, long after the school at Giessen had risen into fame, that in England a sense of our deficiencies in respect to provision for teaching chemistry was felt strongly enough to lead to the establishment of a college of chemistry. At that time the Professor of Chemistry at Oxford was also Professor of Botany. At Cambridge it was thought praise and boast enough that the occupant of the chair of chemistry had, during more than thirty years, frequently resided at the University and every year gave a course of lectures. The Jacksonian professorship was not then, as now, in the possession of a chemist. University College, London, had at this period a very distinguished man in the chair of chemistry, but it was only in 1848 that a commodious laboratory was provided by public subscription, raised in commemoration of the services of Dr. Birkbeck in promoting popular education. In that year Fownes was appointed to co-operate with Graham in the work of teaching, though his premature death soon after left but little time for the fulfilment of the rich promise of his earlier years. At Manchester John Owens had died in 1846, leaving the bulk of his estate for the purpose of establishing a university in Manchester, but as yet the Owens College was not.

The foundation of the College of Chemistry in 1846 was therefore an event of supreme importance in the history of chemical teaching in this country; and though at the time some dissatisfaction was expressed at the choice of the professor selected to direct the work, who, though a distinguished pupil of Liebig, was not an Englishman, all British chemists now concur in believing the choice to have been a most fortunate one. The great majority of my contemporaries having begun, continued, or ended their studies in Oxford Street, they and all who have come under Dr. Hofmann's teaching know how vast was his capacity for work and how marvellous was the power he possessed of communicating his own enthusiasm to his pupils.

Since the time of which I have been speaking the means of instruction in science in England have multiplied enormously. In University College, London, founded in 1828, and in Owens College, Manchester, founded in 1851, not only have chairs of chemistry existed from the first, but they have been occupied by a succession of chemists of the highest eminence. But long after 1846 the whole of the serious teaching of scientific chemistry was accomplished at the College of Chemistry, and it was nigh upon twenty years before the Manchester school began to attract considerable notice.

In 1872-3 the movement set in which has resulted in the erection of colleges for higher instruction at a number of important English and Welsh towns. These,

together with the pre-existent Queen's Colleges in Ireland and the Universities of more ancient foundation in the three kingdoms, are for the most part provided with pretty good laboratories and a competent staff. We have also the Normal School of Science and the Institute raised by the City and Guilds of London at South Kensington, and its Associate College at Finsbury. England is therefore at the present time as well provided with *places* of instruction for the study of chemistry as any country in the world.

And a very large proportion of the professors or heads of the chemical schools in the colleges and universities of the United Kingdom have shown by their own activity in research that they are qualified to give instruction of the highest kind, and are ready to train young chemists in the art as well as in the theory of their subject.

It is therefore no longer true that a student desiring to become a scientific chemist must needs choose between a single institution in London and another in Manchester, or must seek the instruction which he cannot get at home in the laboratory of a foreign university. As an element in a liberal education the position of chemistry is also considerably in advance of what it was twenty years ago.

It is nevertheless true that increased opportunities for study, a considerable supply of capable teachers, and an enormous body of students have not produced such an amount of original investigation, or even of accurate analytical work, as might reasonably be expected. A full and complete explanation of all the influences which contribute to this result would be difficult; but I think the apparent inactivity of the chemical schools in this country is not generally the fault of the professors, but is chargeable in the main to the ignorance, and partly to the indifference, of the public. There exists as yet no intelligent feeling in favour of learning, nor indeed in favour of any sort of education, unless there is expectation of direct returns in the form of obvious practical results. It is this which animates the present popular movement in favour of so-called 'technical' education. That part of the attention of the nation which can be spared from the contemplation of Irish affairs is concentrated upon the problem of how to make every little boy learn the rudiments of chemistry, whether he likes it or not, whilst there are comparatively few people interested in the question of how to provide means and instruction for those who are capable and desirous of attaining to a mastery of the subject. Moreover, the public have not yet grasped this truth, that, so far as chemistry is concerned, it is of very little consequence to the great metallurgical and chemical industries whether the workpeople do or do not know a little chemistry, though it is important that they should be intelligent enough to obey orders. What is wanted is that every manufacturer and manager should himself be an accomplished engineer and chemist, trained to observe, to reason, and to solve problems for himself.

In the case of chemistry this absence of sentiment in favour of concentration and thoroughness, and the demand for superficiality, if only it can be had wholesale, tells in a variety of ways. The governing bodies who control the various colleges and universities, and the public generally, cannot understand that good and useful work is being done unless it can be shown in the form of passes at examinations. Though I most firmly believe in the necessity for examinations, serious mischief begins when they are regarded as the end itself, and not as mere incidents in the student's career towards the end, which should be knowledge.

In respect to chemistry this is the disadvantage which attends the operation of such a system as that of the Science and Art Department or of any system under which certificates in connection with individual subjects are granted on easy terms. Especial objection I also feel to such expressions as 'advanced,' used in reference to a particular stage, so commonly misunderstood as they are by the student and his friends, and operating against his further progress.

Reflect also upon the fact that there are only two or three colleges in this country which can boast of more than one professor of chemistry. In nearly all cases one man is called upon to discharge the duty of teaching classes both elementary and advanced, in pure and applied chemistry, inorganic and organic, theoretical and practical. This is a kind of thing which kills specialism, and

without specialists we can have not only no advance, but no efficient teaching of more than rudiments.

That teachers ought to engage in research at all is by no means clear to the public and to those representatives of the public who are charged with the administration of these new institutions. This was illustrated very painfully a few years ago by the conditions under which professors were engaged at a certain college founded, according to the declaration of its promoters, 'by the people for the people,' wherein it was announced in round terms that original research was not wanted, as the college was 'for the good of the many and not for the advantage of the few.' This example of ignorance is only remarkable by reason of its audacity. Probably many people hold a similar view, though few are bold enough to declare it.

Without going far into the discussion of the general question, which is a large one, I may perhaps be allowed to offer a few remarks for the consideration of any of my audience who may perchance incline towards that opinion.

It is only when a teacher occupies himself with research that the most complete guarantee is given that he is interested in his subject and that he is a learner. A popular mistake consists in regarding a professor as a living embodiment of science—complete, infallible, mysterious—whereas in truth he is, or ought to be, only a senior student who devotes the greater part of his time to extending and consolidating his own knowledge for the benefit of those who come to learn of him, not only what lies within the boundaries of the known, but how to penetrate into the far greater region of the unknown. Moreover, the man who has no intellectual independence and simply accepts other people's views without challenge is pretty certain to make the stock of knowledge with which he sets out in life do service to the end. That one may be fitted to form a sound judgment concerning new theories he must be familiar with the methods by which progress is accomplished. The work of investigation then reacts beneficially upon the work of teaching; that is why teachers should be encouraged, nay even required, to investigate, and not because their discoveries may haply prove to be practically useful.

Of course it may be said that there have been distinguished investigators who could not teach, but the converse is not true; every teacher who has attained to eminence as a teacher, who has drawn men after him, who has founded a school of thought, and has left his mark upon his generation, has been an industrious worker in research of some kind. All teachers cannot be expected to reach the same high standard, but this is the ideal after which all must strive, or fail utterly.

The fact that there is as yet little demand among schoolmasters for high attainments in chemistry is another reason why so little is accomplished in the chemical schools. Here again the public is really to blame. It is disgraceful that in all classes of schools, even where chemistry is supposed to be taught, there are but few places where serious employment is found for the well-trained chemist. I could point to several schools, which claim the position of first-rate, where chemistry is taught by masters who have never studied the subject at all, but who are, I suppose, allowed the traditional 'ten minutes' start' with the book. Would the head-masters of such places dare to employ a person to teach mathematics who did not know the first four rules of arithmetic, or another to teach Latin who had not even got through the accidence? I fancy not. This, however, is without exaggeration the exact parallel of the position in which chemistry is placed in the majority of schools. I have heard the excuse that there is a lack of competent teachers. Of course the demand and the supply will react upon each other. When you offer a reasonable stipend, reasonable accommodation for teaching effectively, reasonable leisure for the master's own studies, and a position on the staff not inferior to that of the classical and mathematical masters, I believe that then, but not till then, there will be as many good school teachers of chemistry as there are of other subjects.

I could point to other prominent schools where the chemistry and other branches of science are taught by a peripatetic South Kensington teacher, who arrives weekly with his box of tricks. Not long ago I was invited to distribute the

prizes given in connection with the evening classes in a town not far from Birmingham, and I took the opportunity of advising the teachers present on the occasion to read. One of them said to me afterwards, 'When do you suppose I can read? I am engaged in going round to my schools from nine in the morning till ten at night.' People of this kind do the greater part of the so-called science teaching sustained by the Science and Art Department, and the worthy town councillors and committees who employ them think that these are the people who are going to help the British manufacturer in his struggle against foreign competition under the guidance of the highly trained chemists from the German universities. This would be ludicrous if it were not so very serious.

There is an opportunity at the present time of correcting some of these mistakes, but no advantage is being taken of it. I refer now to the 'technical schools' which are springing up everywhere. There may be a few competent teachers of chemistry employed in some of them, but I find it difficult to think of many examples. The sort of person who is put in charge of these places is usually a schoolmaster, who is allowed, sometimes even after his appointment, to get a short course of qualitative analysis in order to enable him to obtain a certificate which will entitle him to earn grants from the Science and Art Department.

And manufacturers are much to blame. Instead of employing trained chemists the greater number of those who want chemical assistance are satisfied to engage the services of boys who have been to an evening class for a winter or two.

The difficulty of finding a satisfactory career in connection with the subject also accounts for the fact which I fear must be admitted, that chemistry does not attract its due share of the intellect of the nation. Clever young men can usually do better at the law, in medicine, or in commerce than in teaching chemistry or in manufactures in which chemical skill is applicable. So badly educated are many of the young men who commence the study with professional objects in view that it is quite impossible to teach them anything beyond routine analysis, if so much.

I heard lately from a friend of mine a story of a young groom in his employ who cannot read or write, and who declines to be taught to read on the ground that, considering himself pretty smart, he is afraid that 'learning might dull him.' This idea seems to be rather prevalent among certain classes of people, but I can assure those who wish to be chemists that some familiarity with the rule of three, and such a command of English as will enable them to understand words of more than one syllable, will be no obstacle to the acquisition of chemical knowledge.

Three years has hitherto been regarded as the normal period for study. The question arises, Can a young man, previously well educated, expect to become an accomplished chemist, competent to apply his knowledge usefully, by giving the whole of his time to study during *three years*? I believe not.

By reason of the enormous development of the science the position of the student of chemistry is nowadays very different from what it was thirty years ago. Since that time we have not only got a few new elements, a matter of small importance in itself, but new views of the nature of the elements and of their mutual relations. This could hardly have come about but for the recognition of the law of Avogadro as a fundamental principle, upon which we rely as the ultimate criterion by which the true distinction between so-called equivalent weights and molecular ratios has been established. By the gradual evolution of ideas having reference successively to the electro-chemical relations of elements and compounds, the theory of types, and atomicity or valency, we have arrived at notions of chemical constitution based upon the hypothesis of the orderly linking together of atoms. Thirty years ago isomerism had scarcely attracted notice, and carbon compounds were only just beginning to be arranged in homologous series. The general use at the present day of the language of the molecular kinetic theory shows how deeply this theory influences our ideas of the internal constitution of matter. Within the period referred to dissociation has been studied and a vast body of thermo-chemical data have been accumulated. And although the larger portion of the results of this work still await interpretation, dynamical ideas of chemical action are now generally accepted. We have also new methods of investigation, including spectroscopic analysis with all its vast train of results.

When I began chemistry many of these subjects and others had not been heard of. Of course we had our difficulties, and I well remember the puzzles met with in the endeavour to refer compounds to their appropriate types, also the consternation caused in the student's mind and the confusion in his note-book by the successive changes in the atomic weights of carbon, oxygen, sulphur, and the metals. But on the whole there was much less to learn.

It has always been thought essential that a student of chemistry should have some knowledge of physics. It is now more than ever necessary that this knowledge should be extensive, sound, and based upon a good foundation of mathematics. Thirty years ago a hundred pages of Fownes contained all that was thought necessary, but no one nowadays could be satisfied with that. It is now asserted that a young chemist who expects to find a career in industrial chemistry should also have learnt drawing, and more important still that he should have a good general knowledge of mechanics, steam, and building construction. I suppose everyone will agree in adding French and especially German. You see how the requirements expand.

The inference from all this is that it now takes longer to make a chemist than formerly. This is a point of considerable practical importance.

My estimate that a well-educated and intelligent young man will now require five years for the study of chemistry and accessory subjects before he is likely to be of much use will not appear extravagant.

Here one may remark that in order to become a chemist it is before all things necessary to study chemistry. If the greater part of a student's time is to be taken up with other things it is not very clear how this is to be done.

A reform all round is wanted. The mathematics, modern languages, and drawing properly belong to the antecedent school period, and I believe the Institute of Chemistry would greatly promote the interests of the profession if it would impose upon candidates for the Associateship not only a three years' course of training with an examination in practical chemistry at the end, but a severe examination in mathematics, in the English, French, and German languages, and perhaps drawing before matriculation or registration.

A consideration of the present position of the student of chemistry leads naturally to a review of the methods of teaching the subject. Speaking broadly, I suppose nearly all professional chemists who have had the advantage of systematic training have, up to the present time, passed through very much the same kind of course. This consists, as everybody knows, very largely of analytical work, qualitative and quantitative, preceded or followed by the preparation of a number of definite chemical compounds, besides practice in certain very necessary physical determinations, *e.g.*, relative density of solids, liquids, and gases, melting-points, boiling-points, and so forth. There seems now to be a disposition in some quarters to depart from this time-honoured curriculum in favour of a course in which the student is early engaged in some semblance of investigation, and in which he is encouraged to attack difficult problems, which from their fundamental importance offer considerable temptation. I venture to express a hope that this will not be carried too far. Already we are in danger of losing the art of accurate analysis. One constantly meets with young chemists who are ready enough to discuss the constitution of benzene, but who cannot make a reliable combustion. And according to my own experience attempts at research among inexperienced chemists become abortive more frequently in consequence of deficient analytical skill than from any other cause.

One modification I should gladly see generally adopted. I think an unnecessary amount of time is often spent upon qualitative mineral analysis, and an acquaintance with the properties of common and important carbon compounds ought to be acquired at an early stage. Quantitative work might with advantage be taken up much sooner than usual. By that, however, I mean serious work in which good methods are used and every effort made to secure accuracy. I do not believe in the use of rough methods because they are easy; the use of such leads the student to be satisfied with approximations, which after all he will learn soon enough is all that is possible to man. I am very glad to know that I have the

support of one of my predecessors in this chair (Sir Henry Roscoe), whose opinion will carry far greater weight than mine in deprecating premature efforts to engage students in research.¹

But though it does not appear to me to be wise to encourage beginners, without sufficient experience or manipulative skill, to attempt original work, one of the best possible exercises preparatory to original work is to select suitable memoirs, and not only to read them but to work conscientiously through the whole of the preparations and analyses described, following the instructions given. Many of Dr. Hofmann's papers afford excellent examples. So also do the writings of Dr. Perkin and Dr. Frankland, besides those of many other chemists which could easily be selected by the teacher.

An intelligent student, possessing the requisite preliminary knowledge, would obtain much instruction by repeating the work contained in such papers as the following, for example:—Emerson Reynolds on the missing Sulphur Urea ('J. Chem. Soc.' 1869—i.); Fittig and Tollens on the Synthesis of Hydrocarbons of the Benzol Series (Liebig's 'Annalen,' 1864, cxxxi. 303); L. Claisen and Pupils on the introduction of Acid Radicles into Ketones, &c. ('Berichte,' xx.); Lawson and Collie on the action of Heat on Salts of Tetramethyl-Ammonium ('J. Chem. Soc.' June 1888); Thorpe and Hambly on Manganic Trioxide ('J. Chem. Soc.' March 1888); besides many others, including papers on analytical processes. To such as these there might subsequently be added the determination of an atomic weight on the model of one of the best masters, as a discipline which could not fail to be impressive, and full of instruction.

When chemistry is taught, not with professional or technical objects in view, but for the sake of educational effects, as an ingredient in a liberal education, the primary object is to make the pupil observe and think. But with young students it is very important to proceed slowly, for chemistry is really a very difficult subject at first, owing to the variety of strange materials with uncouth names. To reason from particulars to generals is for the unpractised always a difficult process, and in chemistry this is specially the case. With young students it is, in my experience, preferable to adopt a somewhat dogmatic style, which should of course be exchanged for a more cautious one as the pupil proceeds.

Thus the law of Avogadro can only be given at first as a recognised physical law, without much explanation, since the full apprehension of the evidence upon which it rests can only be secured at a late stage of the learner's progress. There is of course great advantage in the use of an inductive method if only it is employed judiciously. Otherwise the result is only confusion.

A number of papers, pamphlets, and text-books have lately appeared, professing to teach the principles of the science practically and by new methods. Most of these turn out, upon inspection, to be very old methods indeed, but there is a small residue of distinctly original character which are sure to attract, as they deserve, considerable attention. The systems I refer to provide a series of problems which the pupils are called upon to solve. According to this plan the student is not allowed peaceably to examine the properties of oxygen or sulphur which he now sees for the first time. He must weigh, and measure, and observe, and then infer. All this coming at once upon the head of a beginner seems to me to be well fitted to drive him to despair.

I well remember the first experiment in chemistry I ever made. It consisted in dissolving zinc in diluted sulphuric acid in an evaporating dish, lighting with a match the bubbles of hydrogen as they rose, and afterwards leaving the solution to crystallise. I was about sixteen, and the bubbles of gas as well as the crystals I afterwards got interested me very much. If at that time I had been made to weigh the zinc and acid, and measure the hydrogen with the object of answering some question about the composition of zinc and hydrogen sulphates, I should have been pretty much in the position of a boy ignorant of geometry shut up with the propositions of Euclid and ordered to give the demonstrations.

I think when we recall such a fact as that Priestley, who discovered oxygen in 1774, failed to the end of his days to understand the process of combustion, and

¹ See Address to Section B, Montreal meeting.

actually wrote, in 1800, a pamphlet in defence of 'phlogiston,' we ought not to be surprised when young people, though born a century later, fail to perceive at once the full significance of facts to which they are introduced for the first time. At the outset you cannot reasonably expect a young student both to observe accurately and infer justly. These two things must be kept separate at first, and for this reason among others I believe that attempts to make young students verify for themselves the fundamental propositions of chemistry will not be successful. One has only to trace the origin of one's own convictions in reference to any important fact or principle to perceive that they very seldom spring into existence suddenly, but almost always commence in vagueness and hesitation, acquiring consistency and solidity only as the result of accumulated experience.

I will not pretend to determine what may be included within the wide circle of the functions of the British Association; but I think I cannot be mistaken in assuming that the advancement of science is dependent in no small degree upon the provision for the efficient teaching of science. I have traced an outline of what has been done in the past, and have endeavoured to show in what respects I think we are deficient at the present time. No matter how ardent may be the aspirations, how earnest the endeavours of the few, progress will be slow unless they are sustained by the sympathy of the many. On one principle the public must surely insist, that only those shall be allowed to teach who know.

5. *On the Study of Mineralogy.* By T. STERRY HUNT, LL.D., F.R.S.

§ 1. Our knowledge of the inorganic kingdom, as seen in this earth, may be comprehended under geography, geology and mineralogy; the latter in its wider sense including all non-organised forms of matter, with their whole dynamical¹ (physical) and chemical history. In didactic language, however, mineralogy is limited to the study of native species, and includes a knowledge alike of their external characters and their chemical relations. The so-called natural-history method in mineralogy, disregarding these latter, is based exclusively on specific

¹ We use the words dynamics and dynamical in the sense in which they are employed by Thomson and Tait in their treatise on *Natural Philosophy*, wherein all those manifestations of force which are neither chemical nor vital (biotic), including, besides ordinary motion, the phenomena of sound, temperature, radiant energy, electricity and magnetism, are embraced under the general title of dynamics, corresponding to what in popular language is designated Physics. Other eminent students of our time have sanctioned this use of the term dynamics, in which they were to a certain extent anticipated by Berzelius, who in 1842 included electricity, magnetism, light and heat—all of which he regarded as affections of matter, and compared their phenomena with those of sound—under the common term of *Dynamides*. (See Hunt, *Mineral Physiology and Physiography*, p. 13.)

gravity, hardness, optical characters, texture and structure, including crystallisation; while the chemical method regards the results of chemical analysis alone, and mixed methods consider these in connection with crystallisation, and even endeavour to take into account other physical characters. The defects of all the methods hitherto devised are obvious, and no system of classification can be complete which does not assign a value and a place to all characters whatsoever. There exists in the nature of things such an interdependence of these that a true natural system can exclude none. To the establishment of such a system, a clearer view of the nature and relations of physical and chemical phenomena than that generally received will materially aid us.

§ 2. Matter is susceptible of changes of volume of two kinds:—(1) Those produced from without, by variations of temperature and of pressure, which changes are constant and regular. Effecting no essential alteration in species, they may be called *extrinsic* or, as the result of external dynamic agencies, *mechanical* changes. (2) Those which have been described as due to 'internal disturbances,' which effect specific alterations in character. These constitute *chemical* or what may be called *intrinsic* changes, and differ from the last in that, instead of being constant and regular, they are periodic and subordinated to definite and unforeseen relations of volume. Intrinsic changes of volume in matter connote chemical as distinguished from dynamical processes. In chemical union we have intrinsic contraction or condensation (variously designated as interpenetration, compenetration, identification, integration, unification); and in chemical decomposition, intrinsic expansion or division. These changes may be either homogeneous, involving one species of matter, or heterogeneous, involving two or more species. The first includes so-called polymerisation and depolymerisation, which may be described as homogeneous intrinsic union and homogeneous intrinsic division; constituting what we have called collectively *chemical metamorphosis*. Those intrinsic changes which involve two or more species we have included under the title of *chemical metagenesis*; the process being one of heterogeneous intrinsic union or of heterogeneous intrinsic division. In the former, intrinsic contraction involves volumes of unlike species, and in the latter, intrinsic expansion resolves a species into two or more unlike species. The relations to volume of all such changes are most simple and evident in the case of gases and vapours; but the same laws of intrinsic contraction and expansion by volumes apply alike to gases and to the liquid and solid species formed by their condensation. In all of these chemical changes temperature and pressure play an important part, and beyond certain limits the extrinsic or dynamic changes thereby produced themselves provoke chemical changes. These in their turn are accompanied by thermic changes, the study of which is the object of thermo-chemistry.

§ 3. All chemically stable forms of matter may theoretically, by sufficient elevation of temperature, assume, even under the greatest pressure, a gaseous condition; the more or less dense polymeric vapours thus produced being subject to intrinsic expansion or depolymerisation on diminution of pressure. By reduction of temperature these pass, as may be seen under favourable conditions, through successive polymerisations, or processes of intrinsic contraction, into liquid (or solid) species; the passage from the vapour to the liquid being apparently continuous. The ideal gas is wholly obedient to the dynamic influence of pressure, according to Boyle's law, to which the ideal solid is wholly indifferent. These ideal forms are, however, constant only within certain limited ranges of temperature and pressure, beyond which even the so-called permanent gases become liquid or solid by intrinsic changes.

The regularity of the extrinsic variations in volume for gases and vapours, within certain known limits, enables us for such bodies to determine their specific gravity, for which purpose atmospheric air at 0° and 760 mm. is taken as unity. If for this we substitute hydrogen gas (represented as $H_2 = 2.0$), the lightest body known, at the same temperature and pressure, the specific weight of an equal volume of any given vapour or gas, calculated for this standard temperature and pressure, is its equivalent weight, or in the language of the popular hypothesis, the molecular weight of the species. Extending the same method from normal gases -

and vapours to polymeric vapours, and thence to liquids and solids, and remembering that none of these forms are stable beyond certain ranges of temperature and pressure, we proceed to determine the specific gravity of all such bodies in terms of the same gaseous unit; the number thus obtained being for each body its equivalent weight. We thus find, as has long been suspected, that the equivalent (or so-called molecular) weights of liquid and solid species are exceedingly elevated. That of water, a litre of which at 100° (its temperature of formation under a pressure of 760 mm.) weighs 958.78 grams, corresponds to 1192 volumes of water vapour at standard temperature and pressure ($H_2O = 17.96$) condensed into a single volume; or to $1192 \times 17.96 = 21,408$, approximately 21,400. Representing by p the empirical equivalent weight, which is really the specific gravity on the hydrogen basis ($H_2 = 2.0$), and by d the specific gravity taking water = 21,400 as unity, we obtain by the formula $p \div d = v$, the reciprocal of the coefficient of the condensation which takes place in the passage of a normal gaseous species, by intrinsic contraction or polymerisation, into the liquid or solid species; the specific gravity of which we have determined by comparison with water.

§ 4. The reciprocal number thus got is, as we shall show, one of great significance. In determining the specific weight of any given liquid or solid species, the fact of prime importance is not simply its specific gravity as compared with water, but the relation of the value thus determined to the equivalent weight, or, in other words, to its specific gravity on the hydrogen basis. It is not d , nor yet p , but the relation $p : d$, as expressed by v . In the case of volatile species the true value of p may be known, but for the comparison of fixed solids, as oxyds, carbonates, and silicates, we deduce from the received formulas an arbitrary value for p by dividing the value calculated therefrom by twice the number of oxygen portions. Thus for MgO , $p = 40 \div 2$; for SiO_2 , $p = 60 \div 4$; for Al_2O_3 , $p = 102 \div 6$; for $SiMg_2O_4$, $p = 140 \div 8$; for $CCaO_3$, $p = 100 \div 6$. For metalline minerals, including metals, and their compounds with S, Se, Te, As, Sb, Bi, the value assumed for p is that got by dividing the empirical equivalent weight by the sum of the valencies.

While the specific gravity of liquid and solid species is represented by d , the hardness, infusibility and insolubility or resistance to chemical change are, for related species, directly as the condensation, or inversely as the value of v . This may be seen in comparing colourless ordinary phosphorus, $v = 17.2$, with the metalloidal form, $v = 13.2$; the isomeric silicates, meionite, $v = 6.5$, and zoisite, $v = 5.3$; or calcite, $v = 6.2$, with dolomite, chalybite and diallogite, $v = 5.2$, and with magnesite and smithsonite, $v = 4.7$; for aragonite, $v = 5.55$. These examples will serve to show the relations between sensible characters and chemical constitution, the interdependence of which must be taken into account in a natural system of mineralogical classification. The differences in hardness and in solubility of the different species just named are familiar to chemists. The behaviour of native silicates with fluorhydric acid, lately studied by J. B. Mackintosh, illustrates in a striking manner the relations between condensation and solubility.

§ 5. The successive forms imposed upon matter give us the order in which such a system of mineralogy should be built up. First, the form which we may call the *chemical form* of the species, either elemental or compound, due to the unknown stochiogenic process, or to subsequent chemical metagenesis. Second, what may be called the *mineralogical form*, which involves the greater or less intrinsic contraction (polymeric condensation) of the normal chemical species—often gaseous or volatile but frequently unknown to us—and the assumption by it of a liquid or solid state, having greater or less specific gravity, hardness, fixity and insolubility, and being metallic or non-metallic, colloidal or crystalline. Third, the *crystalline form*, being the geometric shape assumed by the crystalline individual, which connotes a certain structure, apparent in the cleavage, the varying hardness, and the thermic, optical and electrical relations, of the crystal, but is, notwithstanding its value in determinative mineralogy, the least essential or most accidental form of the mineral species. The significance involved in the note of metallicity is very apparent when we consider the metallic and non-metallic conditions of selenium and of phosphorus, the similar dual conditions of the sulphids of mercury and antimony, the non-metallic and sparry characters of the native sulphids of zinc,

cadmium and arsenic, and the singular metallic character assumed by the complex tungstates or Tungstometalloids, known as tungsten bronzes. These, with the not less remarkably complex soluble tungstates or Tungstosalinoids, and the native tungstic species, make the Tungstates one of the most instructive orders known.

§ 6. The author has elsewhere proposed to divide the mineral kingdom into four classes, including (1) Metalline, (2) Oxydised, (3) Haloid, (4) Pyricaustate (combustible or fire-making) species. Each of these classes is again divided into orders, tribes, genera and species. In the first class a single order includes two sub-orders and nine tribes, named (1) Metalloideæ; (2) Galenoideæ, including three sub-tribes corresponding to sulphur, selenium and tellurium compounds; (3) Bournonoidæ; (4) Pyritoideæ; (5) Smaltoideæ; (6) Arsenopyritoideæ; (7) Spatometalloideæ; (8) Sphaleroideæ; (9) Proustoideæ; each tribe including one or more genera. Again, in the second class are grouped under different orders, Oxyds, Silicates, Carbonates, Borates, Sulphates, Phosphates, Tungstates, &c. Three sub-orders of silicates include protoxyd, proutoperoxyd and peroxyd silicates; among peroxyd bases being reckoned aluminic, ferric, manganic, chromic, bismuthic, and also, for special reasons, zirconic oxyd. Recognising in each sub-order various types designated Hydrospathoid, Spathoid, Adamantoid or gem-like, Phylloid or micaceous, and Porodic or colloidal; the tribes may be named Pectolitoid, Willemoid, Amphiboloid, Talcoid, Ophitoid, Zeolitoid, Feldspathoid, Granatoid (garnet-like) Micoid, Pinitoid, Perzeolitoid, Eulytoid, Topazoid, Pyrophylloid and Argilloid. Soluble saline species in any order are referred to a salinoid type, as Borosalinoid, Tungstosalinoid. The extension of this system to the Haloid and Pyricaustate classes is easy, and has been elsewhere explained.

The work of arranging in genera and species, with a Latin binomial nomenclature, and the determination for each species of the value of v , is now nearly completed for the first two classes; and the whole will probably soon appear, with a proper introduction, as a Systematic Mineralogy, to be followed by a Descriptive Mineralogy. The general principles here set forth are discussed at length in the author's 'Mineral Physiology and Physiography' (Boston, 1886), pp. 279–401, where, in a chapter entitled 'A Natural System in Mineralogy,' will be found an examination of the constitution and relations of the known natural silicates arranged in tribes, and tabulated, with the calculated values of v , and a new quantivalent chemical notation. See farther, a paper on 'The Classification and Nomenclature of Metalline Minerals,'¹ discussing Class I., in the 'Proceedings of the American Philosophical Society,' for May 4, 1888, reprinted in the 'Chemical News' of August 10 and 17; also the author's 'New Basis for Chemistry,' 2nd edition (Boston, 1888), where, in chapters vii. and xiv. many points in the proposed mineralogical classification are elucidated.

6. *On the Logarithmic Law and its Connection with the Atomic Weights.*
By Dr. G. JOHNSTONE STONEY, F.R.S.

7. *On Dissociation.*² By the Rev. A. IRVING, D.Sc., B.A.

The author refers to the paper on this subject which he read before Section B at the Birmingham meeting in 1886. Further work has furnished confirmatory evidence in support of the theory then propounded. From a number of experiments recently made, visible evidence has been obtained of the direct dissociation of the hydrocarbons of coal-gas. The deposition of amorphous carbon takes place in contact with pumice-fragments at temperatures ranging from dull red heat up to the incipient fusion-temperature of the hardest Bohemian glass. Along with carbon some sulphur is also deposited. We have thus a visible confirmation of

¹ An abstract of this paper, printed in the programme of the Royal Society of Canada, without revision or correction by the author, will also be found in the *Chemical News* for June 29, 1888.

² Published *in extenso* in the *Chemical News*, No. 1505, September 28, 1888.

the theory put forward two years ago in the two cases of the hydrocarbons and the sulphur compounds of coal-gas; the cause of the deposition of 'gas-carbon' is explained, and the operations of the same physical principles is believed to have been the origin (for the most part) of the graphite which abounds (in places) in the (archæan) primitive crystalline rocks. Reference is made to the presence of hydrocarbons in heads of comets and of carbon in meteorites.

8. *On Closed-chain Formulæ.* By J. E. MARSH, B.A.

9. *On Van't Hoff's Hypothesis and the Constitution of Benzene.*
By J. E. MARSH, B.A.¹

FRIDAY, SEPTEMBER 7.

The following Papers were read:—

1. *Discussion on the Chemical Problems presented by Living Bodies, opened by Professor MICHAEL FOSTER, Sec.R.S.*

2. *On the Atomic Weight of Oxygen.*
By ALEXANDER SCOTT, M.A., D.Sc., F.R.S.E.

After giving a brief historical sketch of the work which had been done to determine with the greatest possible accuracy the atomic weight of oxygen—that of hydrogen being taken as the unit—the author pointed out amongst other sources of error that the presence of air to the extent of only $\frac{1}{5000}$ of the volume of hydrogen used would be sufficient to raise the value 15.96 deduced from Dumas' experiments to 16.00. Similarly with regard to Regnault's ratio of the densities originally given as 15.96 also, but shown by applying the correction proved necessary by Lord Rayleigh when recalculated by Crafts to be only 15.91, the presence of $\frac{1}{2500}$ of air by volume in the hydrogen would be alone sufficient to account for this being so far below 16, to say nothing of the traces of water vapour and sulphur dioxide also most probably present.

The recent work of Professor J. P. Cooke and Mr. Richards, as well as the re-determination of the ratio of the densities of the gases by Lord Rayleigh, have tended to remove the value for the atomic weight of oxygen further from 16 instead of raising it, the corrected number of Professor Cooke being 15.869. Lord Rayleigh's ratio of the densities being 15.884, and if we take 1.998 : 1 as the ratio of the volumes in which hydrogen and oxygen combine to form water, we get from it 15.90 as the atomic weight of oxygen.

The author then described his latest experiments on the ratio of the combining volumes of hydrogen and oxygen and pointed out that the volume of hydrogen required seemed to decrease when it was continuously evolved from the same vessel, four consecutive experiments with hydrogen from the electrolysis of dilute hydrochloric acid with zinc amalgam giving

H	O	Total Impurity	Date
2.001	: 1	$\frac{1}{8776}$	May 2, 1888
1.999	: 1	$\frac{1}{4806}$	May 5, "
1.998	: 1	$\frac{1}{16176}$	May 5, "
1.995	: 1	$\frac{1}{31576}$	Aug. 31, "

¹ Published *in extenso* in *Phil. Mag.* November 1888.

The hydrogen seemed to be quite free from every trace of hydrochloric acid, but the continuous variation of the ratio seems to point to the presence of some impurity at present undetected but which seems to be gradually eliminated as the gas in the last case is the purest. The lower the value for the hydrogen volume gives of course a higher value for the atomic weight of oxygen.

The author concluded by remarking that it was still premature to conclude that the atomic weight of oxygen was below 16, as almost all the errors in both Dumas' and Regnault's methods could only lower the number, very few raise it.

3. *The Incompleteness of Combustion in Explosions.*

By Professor H. B. DIXON, *F.R.S.*, and H. W. SMITH, *B.Sc.*

The authors found that when a mixture of two volumes of hydrogen and one volume of oxygen was exploded in a long tube an explosive residue was left unburnt which could be collected and exploded.

The percentage of explosive residue found depended partly on the surface of the vessel in contact with the gas; in a narrow tube 4.5 mm. in diameter nearly 2% of electrolytic gas remained unburnt, while in an iron cylinder 100 mm. in diameter about 5% of electrolytic gas remained unburnt.

The same phenomenon of incomplete combustion was observed in the case of moist carbonic oxide and oxygen.

4. *A new Gas Analysis Apparatus.* By W. W. J. NICOL, *M.A., D.Sc.*

This apparatus consists of a measuring tube and laboratory vessel of the same diameter placed side by side in an outer jacket of water. The two tubes are connected by U-shaped capillaries at top and bottom. The upper capillary is furnished with an ordinary three-way stopcock which communicates with a cup on the top through which gas or various reagents may be introduced or expelled through a siphon tube. The lower capillary has also a three-way tap, which is, in addition, bored longitudinally, by means of which communication can be established between either the laboratory tube or the measuring vessel and one or other of two movable reservoirs, one of which during use is always level with the top of the apparatus, the other being at the bottom. The apparatus is intended to supply the want of a quick method, comparable in the way of accuracy with the well-known method of Bunsen.

5. *The Determination of Vapour-densities at High Temperatures and under Reduced Pressure.* By Dr. WILLIAM BOTT, *F.O.S.*

About a year ago a method was described by the author for the determination of vapour-densities by accurately measuring the increase of pressure caused by the volatilisation of a weighed quantity of substance in a calibrated vessel connected with a mercury pressure-gauge and heated in the manner employed in Hofmann's method. The determinations by this method could be made at any pressure required, but we must refer to the original paper ('Ber.' xx. 916) for the details. Now the range of temperatures at which the original method can be used is naturally a limited one from the plan of heating adopted. By slightly altering the apparatus and the *modus operandi*, however, this objection can be overcome, and the apparatus may be heated in an open bath, or even in a furnace in the manner adopted by Victor Meyer. The original apparatus (see 'Ber.' xx. 916) is made shorter, with a bulb about 30 ctm. by 4.5 ctm., corresponding to 450 cc. capacity. The remainder of the apparatus remains unaltered, excepting that a stopcock is inserted between the gauge and the vessel, so that communication can be shut off at any time. This having been done at the commencement of the determination, the initial temperature of the apparatus (*viz.*, the ordinary temperature) is noted, and from this and the known capacity of the vessel the volume of air calculated which it contains. The apparatus is then heated till constant, and

the expansion up to that point determined by collecting and measuring the air expelled on heating. From this volume the temperature is again calculated. Communication with the gauge is then made and the apparatus quickly exhausted as far as may be thought requisite. The remainder of the operation is the same as in the old method already referred to, the density being found from the formula

$$d = \frac{s}{0.00008958 \left[(C - \frac{OP}{P_1}) (\frac{P}{760(1 + 0.00367t^0)}) \right]}$$

(s = substance; C = capacity of apparatus; P = initial pressure; P_1 = final pressure; t^0 = temperature during experiment.)

The main objection to the above method might lie in the fact that its accuracy decreases with the pressure employed (see original paper, 'Ber.' xx. 916). Experiments having been made to find a more direct method, the following arrangement was found to answer all requirements. A large Victor Meyer's apparatus, with a bulb 30 ctm. long by 4.5 ctm. diameter, is used, fitted with a detachable top-piece, communicating with a barometer tube and a large measuring tube about 40 ctm. long by 3 ctm. diameter, and connected with a mercury reservoir. The apparatus is heated till constant, exhausted as far as may be requisite, and the reservoir so adjusted that the measuring tube is completely filled with mercury. The pressure, as shown by the barometer tube, is then noted, substance introduced, and the surplus pressure generated is removed by lowering the reservoir till the gauge again registers the initial pressure. The volume of gas in the measuring tube is then determined, and from it the density calculated as in Victor Meyer's method. Neither the temperature of the bath nor the exact capacity of the apparatus need be known. The results are accurate.

An apparatus like the above, only made of suitable material, and slightly adapted to suit special requirements, might be used for the study of dissociation at very high temperatures and varying pressures.

6. *On Photographing Hydrogen and Chlorine Bulbs by aid of the Flash of Light which caused their Explosion.* By Professor P. PHILLIPS REDSON, D.Sc.

The notices which have appeared in 'Nature' (vol. xxxvii. p. 576; vol. xxxviii. p. 15) of O. du Bois Raymonde's successful attempt to photograph the expanded pupil of the eye by a flash of magnesium suggested to my mind the experiment of attempting to photograph a glass bulb containing a mixture of equal volumes of hydrogen and chlorine, which, as is well known, combines with explosive violence and consequent shattering of the bulb when exposed to the flash of magnesium light.

At my suggestion, Mr. Saville Shaw, demonstrator in chemistry at the Durham College of Science, Newcastle-upon-Tyne, undertook the experiment, with the result (as shown in the accompanying photograph) that a clearly defined image of the bulb can be obtained, although the bulb itself is shattered by the explosion.

The method of procedure was as follows. An empty bulb similar to the one to be exploded was clamped in a stand and accurately focussed in gaslight. The room was then completely darkened, the empty bulb replaced by one containing the mixed gases, and after uncovering the lens combination was induced by the ignition of a mixture of magnesium dust and potassium chlorate placed close to the bulb. In this way two bulbs have been photographed, one of which is exhibited. It will be seen on close examination that, whilst the outline of the bulb itself is perfectly clear, it is fainter than the jagged stem which was left unbroken, and consequently exposed for a much longer time than the bulb. A small mirror was attached to the bulb with the intention of reflecting the light into the camera. The result, however, shows that this was quite unnecessary, and the only effect of this arrangement has been its reproduction in the photograph.

It is proposed to make further experiments in this direction, which may perhaps throw some light on the question of photo-chemical induction.

7. *On the Formation of Crystals of Calcium Oxide and Magnesium Oxide in the Oxyhydrogen Flame.* By J. JOLY, M.A., B.E.

Lime cylinders which have been in use for some time in the production of the lime-light will be found to have undergone alteration in structure in the immediate vicinity of the part played on by the flame, becoming lustrous and crystalline. With the lens it is seen that the reflecting faces are squares. By playing on a small heap of fragments of pure lime with the oxyhydrogen flame larger and very distinct cubes are easily produced. The crystals are very evidently formed by sublimation. They build upon the rough surface of the lime in arborescent growths of cubes and cubo-octahedrons, having a common orientation. They are limpid or milky, very lustrous, showing a plated structure on the cube face and appear to offer a greater resistance to hydration than the amorphous substance. In the polariscope they are optically inactive. Up to the present CaO seems to have only been crystallised from the nitrate (Brügelmann).

In a similar manner, but with more difficulty, minute transparent cubes of magnesium oxide may be prepared from the amorphous substance.

SATURDAY, SEPTEMBER 8.

The following Report and Paper were read:—

1. *Report of the Committee on the present methods of teaching Chemistry.*
See Reports, p. 73.

2. *Chemistry as a School Subject.* By the Rev. A. IRVING, D.Sc., B.A.

The author expressed some doubt as to the means adopted by the committee appointed last year for dealing with this matter in our public schools, and strongly urged considerable addition to the committee of men who, as science-masters, have first-hand knowledge of the facts. Speaking from a personal experience of some twenty years, both as a schoolmaster and as a teacher of science, he deprecated any attempt by syllabus or otherwise to fetter the freedom of action which every real educator knows to be one of the first conditions of fruitful educational work. The high educational value of experimental science alone considered tells us that this must be our guiding principle in dealing with chemistry as a school-subject; we must not aim at making all our boys professional chemists; we must defer in this matter to the higher educational law expressed in the formula, '*Mens sana in corpore sano.*' The slur cast indiscriminately upon the public schools in a paper read last year was repudiated, and the practical inapplicability to the necessary conditions of school-work of many suggestions contained in that paper was pointed out. The alleged sterility of English chemical science was referred rather to a divorcement in the past between the laboratory-worker and the higher culture of the country, and it was maintained that the remedy lies mainly in the recognition of the true importance of the subject by the older universities, with a further development of the professoriate, which (with the healthy rivalry of numbers) is the true secret of the working productiveness in science of the German as compared with the English academical system. It was suggested that the committee would do well to select a fairly large number of real contributors to the science in the last quarter of a century and attempt to arrive inductively from the facts of their individual biographies at some general conclusions as to what intellectual antecedents and environment seemed to enter most essentially into the *genesis* of the scientific chemist; while the strongest possible appeals should be made to the ancient universities to lead public opinion, especially the governing-bodies of our public schools, to recognise genuine work in science and proved capacity in

educational work as constituting equal claims with mere 'scholarship' in the appointment of head masters.

Some recent depreciations of qualitative analysis were remarked upon, analysis rationally taught being held to be a good mental discipline available for class-teaching, and a sort of stock on which might be engrafted a great deal of theoretical as well as experimental teaching, the work of the lecture-room and the exercises of the laboratory being made each to supplement the other. With the cry that the great difficulty is the want of good text-books the author has no sympathy; experimental science can only be really taught by men who are independent of such extraneous aids. The common notion that experimental science is a 'refuge for the destitute' in intellectual matters was strongly denounced as an absurd fallacy, the admission of which is nothing more nor less than the practical surrender of our position to the 'classical' and 'mathematical' men who make up the majority of the staff of every public school.

The author dealt with the 'objects,' 'difficulties,' and 'methods' of teaching chemistry; but on these points many of his suggestions had been already put forward in the committee's printed report.

The remainder of the paper dealt with examinations, and various suggestions were made as to how these might be improved, so as to discourage the mere exercise of the faculty of receptivity for examinational purposes, and to place examinés who had been brought into touch with scientific research and had had the spirit of inquiry awakened in them at a greater advantage than at present.

MONDAY, SEPTEMBER 10.

The following Papers were read:—

1. *Discussion on Valency, opened by Professor H. E. ARMSTRONG, F.R.S.*
2. *Evidence of the Tetravalency of Oxygen derived from the Constitution of the Azonaphthol-Compounds. By Professor R. MELDOLA, F.R.S., F.C.S., F.I.C.¹*

The author commenced by pointing out the differences between the azo-derivatives of α -naphthylamine and α -naphthol as compared with the corresponding azo-compounds of the β -series. The α -derivatives have all the properties of amidoazo- or oxyazo-compounds, and show in all their reactions the presence of NH_2 or HO . The β -compounds, on the other hand, not only differ from the others in physical properties, such as melting-point and crystalline form, but in their chemical properties they show much less distinctly the presence of NH_2 and HO . They are diazotisable only with much difficulty, and the insolubility of the oxy-compounds in aqueous alkalies appears to indicate the absence of hydroxyl.

The author next proceeded to review the different formulæ which had been proposed for the compounds of the β -series, the first attempt to represent these on a different type to the α -compounds having been made by Liebermann (I.), himself (II.), and Zincke (III.):—

Since these were suggested in 1883–4 evidence has been accumulated which the author considered as being distinctly unfavourable to the proposed formulæ. It has been found by Nietzki and Goll, and by Zincke himself, that the azo-deriva-

¹ Published *in extenso* in the *Phil. Mag.* Nov. 1888.

tives of β -naphthylamine can be diazotised and the diazo-salts converted into the corresponding oxy-compounds by the usual reaction.

The author and F. J. East have recently found that the nitrobenzeneazo- β -naphthylamines can be converted into the corresponding β -naphthyl-acetates by heating them with acetic acid and adding sodium nitrite. Weinberg has shown also that benzeneazo- β -naphthol can be ethylated, and the author and F. J. East have shown that this and other β -naphtholazo-derivatives can be acetylated. The reduction products of the ethyl and acetyl derivatives tend to show that the alkyl or acetyl is not attached to the N-atom, as would be required by Zincke's hydrazone formula or by Liebermann's formula, but further investigation in this direction is considered necessary, and is being undertaken in the author's laboratory.

The author next pointed out that although the results of the most recent experiments thus appeared to favour a return to the old formulæ—

the non-phenolic character of the β -oxy-compounds and the other differences shown by these and the β -amido-compounds when compared with those of the α -series, must still be considered as evidence of a different constitution. To express this difference in the case of the orthoamidoazo-compounds it is suggested that the N : N-group and the NH_2 , being in the ortho-position, interact with the formation of a closed chain, and the author proposes for these and the analogous oxy-compounds the general formulæ—

The first of these expressions shows the relationship of the orthoamidoazo-compounds to the azimides of Griess into which (or into isomeric substances) they can be converted, as shown by Zincke, by the action of oxidising agents, the latter simply removing two atoms of hydrogen and leaving

The same formula explains the difficultly diazotisable character of the compounds, their feebly basic properties, and the formation of ortho-diamines by reduction.

The second formula, in which oxygen is represented as tetravalent, appears to accord with the general properties of the β - or ortho-oxyazo-compounds. Thus it is seen that the replaceable hydrogen atom is attached to the oxygen, but is not in the hydroxylic state, as the oxygen forms one atom in a closed ring. This may be the explanation of the non-phenolic character of these compounds. With reference to the tetravalency of oxygen the author called attention to Friedel's compound $(CH_3)_2O.HCl$, as well as to the general arguments based on the position of the element in the periodic system.

3. *The Theory of Solution.*¹ By T. STERRY HUNT, LL.D., F.R.S.

The author began by a brief statement of Mendeléef's views on solution, as put forth since 1886 and resumed in the latter's recent paper on the compounds of ethylic alcohol and water, presented to the Chemical Society of London in 1887. In this it is maintained that the products of the dilution with water of bodies like alcohol and sulphuric acid include several distinct chemical compounds, with greater or less proportions of water, which compounds may in some cases be separated as definite crystalline solids by reduction of temperature. Their presence is also made evident by the study of the relation of the specific gravity to the con-

¹ Published in *extenso* in the *Chemical News* for Sept. 28, 1888.

tesimal composition of the dilute alcohol or acid. The author noted further the confirmation of these views by the subsequent studies of Crompton on the electrical conductivity of diluted sulphuric and other acids, and of solutions of the hydroxyds of potassium and sodium, as well as to the able discussion of these results lately published by Professor H. E. Armstrong.

He then proceeded to recall his own contributions to the theory of solution, dating from 1853, in which he has affirmed the chemical nature of solution, and especially his essay entitled *Thoughts on Solution and the Chemical Process*, in the 'Chemical Gazette' for 1855. It was therein maintained not only that solution is a chemical process, but that 'all chemical union is nothing else than solution. The uniting species are, as it were, dissolved in each other, for solution is mutual;' and subsequently that 'the type of the chemical process is found in solutions, from which it is possible, under changed physical conditions, to regenerate the original species.' After giving an analysis of the paper of 1855, its conclusions are resumed under the following heads: 1. The conception that in the process of aqueous solution there are formed definite compounds with water, accompanied by all the phenomena of chemical union. 2. That in these compounds of a single proportion of a salt or other species with many proportions of water there are clearly defined limits beyond which the further addition of water gives rise (A) to decomposition involving a new arrangement of the elements of the previously united bodies (double decomposition), or (B) to simple admixtures of one definite solution, or liquid species, with another less dense solution, or with water. 3. That these compounds are separable in a solid state by changes of temperature and (theoretically at least) in a liquid state, by the influence of gravity. 4. That liquidity is but an accident of solution, since it is a state depending on temperature and on pressure, which state may be assumed by all species, whether elemental or compound.

The author then proceeded to notice his later treatment of the subject in his 'New Basis for Chemistry,' and especially in the second (revised and augmented) edition (Boston, 1888). Therein are considered the cryohydrates of Guthrie, and the remarkable liquid compounds of salts with small quantities of water, got by Tilden and Shenstone at high temperatures under pressure. He further notes the evidences of the integral vaporisation of solutions above the critical point, under pressure, observed by Hannay and Hogarth, and the previous separation of some of these at high temperatures into lighter and denser layers. Earlier observations of similar separations, and the recent studies of Traube and Neuberg on the differentiation by gravity of various saline solutions in dilute alcohol, are also noticed. All of these facts are considered as illustrations of the theory of solution so long maintained by the author, which, at least so far as aqueous solutions are concerned, is now adopted by Mendeléef.

4. *The Composition of Copper-Tin Alloys.* By A. P. LAURIE.

Experiments by Lodge, Roberts-Austen, &c., have shown that the physical properties of these alloys point to the existence of two compounds, Cu_3Sn and Cu_4Sn .

In testing the E.M.F. of these alloys in constant voltaic cells the author finds a change of E.M.F. corresponding to the formula CuSn , and by suitable arrangements has succeeded in eating out the excess of free tin in an alloy, leaving the compound Cu_3Sn behind.

5. *The Composition of the ancient Roman Mortar from the London Wall.* By JOHN SPILLER, F.C.S.

With the view of collecting fresh evidence as to the chemical union of lime and silica by long contact, the author had examined a sample of ancient Roman mortar taken from the section of old London Wall recently laid bare in St. Martin's-le-Grand.

From the fact that a large quantity (11 per cent.) of silica could be dissolved out readily by caustic soda, and there being a deficiency of carbonic acid without

any evidence of free caustic lime, the author considered he was justified in drawing the inference that silicate of lime was present, this body being the result of direct combination between lime and sand in the course of many centuries.

Samples of a London mortar about a hundred years old and another of recent date contained 1.1 per cent., or less, of soluble silica, that is, only one-tenth of the amount now actually found in the Roman mortar analysed.

For full particulars of composition and analytical details see the 'Chemical News' of October 19, 1888, p. 189.

6. *On the Rate of Solution of Copper in Acids.* By V. H. VELEY, M.A.

From time to time accounts of experiments have been published on the rate of solution of metals in acids. In most cases a piece of metal of more or less regular surface is placed at the bottom of a suitable vessel, dilute acid poured thereon, and the rate measured at which the hydrogen or other gas is evolved. It is obvious that the measured result is one of very mixed causes, the separate effect of which has not been duly taken into account. Thus the rate at which hydrogen is given off from redistilled zinc and dilute sulphuric acid will depend *inter alia* on (i) the surface of metal exposed; (ii) the concentration of the acid; (iii) the rate of diffusion of the solution of salt formed in the acid liquid. Of these only (i) can be approximately constant, while (ii) and (iii) are indeterminable variables.

The author has made a series of experiments on the rate of solution of spheres of electrolytic copper, made from one block, in solutions of potassium bichromate acidulated with sulphuric acid under such conditions that not only are fresh surfaces of the copper continually exposed, but also the dissolving liquid in the immediate vicinity of the metal continually renewed. At the end of definite intervals of time the loss in weight of the sphere is determined, and the alteration in area calculated by a measurement of the axes of the sphere. The mass dissolved per unit area is taken as the measure of the rate of solution.

As a preliminary step it was ascertained that, under the same conditions, different spheres of copper dissolved at the same rate.

Experiments thus far have shown that the difference of the logarithm of the factor $\frac{M}{A}$ (M = mass, A = area) is constant for a constant difference of temperature.

But, apparently, the value of this factor is proportional only within certain limits to the concentration; thus, although with greater or less concentration the mass dissolved is greater or less, yet this variation proceeds *per saltum*, and not in direct proportion, even though a large excess of dissolving reagents was in all cases used.

The rate of solution is also dependent upon the rate of movement of the metallic sphere in the acid; throughout the experiments this has been kept constant by various mechanical arrangements.

7. *Recovery of the Ammonia and Chlorine in the Ammonia-soda Process.* By F. BALE.

If ammonium chloride be volatilised, and its vapour passed over or through heated metallic oxide, at a temperature of 400° C. or higher, the ammonia which is evolved is partially decomposed in its passage over the heated oxide, and this to the extent of from 25 to 50 per cent. of the ammonia evolved.

If, however, the ammonium chloride be intimately mixed in powder with metallic oxide in powder, as the oxide of manganese (which I prefer), and the mixture then gradually heated, the ammonia is gradually and completely evolved at a temperature of 130° C. to 325° C. without the loss mentioned above by the method of volatilisation of the ammonic chloride. Most of the ammonia is here evolved between 130° and 200° C.

In this method of mixtures, if the temperature of the residue left after the evolution of the ammonia be kept below 350° C. and cold and dry air be passed

over it, no chlorine is evolved at this temperature, but residual ammonia and moisture may be completely driven out of the retort on stirring the mixture. If the temperature be now raised to 350°C ., the chlorine begins to be slowly evolved on the passage of dry air, when the oxide used has been manganese; and the percentage yield of chlorine by the peroxides of manganese is about one and a half time that of any monoxide. Sesquioxides (M_2O_3) are unsuitable for this purpose, as they yield one-third less ammonia, the other third being decomposed into nitrogen and hydrogen.

The method of volatilisation of the ammoniac chloride means a high temperature, which means again a loss of ammonia and other disadvantages. By the method of mixtures a low temperature is employed, the ammonia saved, the chlorine fully evolved, and atmospheric air may be used to expel residual ammonia and steam remaining in the retort; and if the temperature be kept below 350°C . air may be passing through the retort during the whole operation for the ammonia, thus removing the ammonia and steam as formed, and preventing loss of ammonia and the formation of hydrochloric acid when chlorine is required.

Oxides of the heavy metals, and the alkaline earths and salts formed from these, may be used for this purpose with more or less advantage. There is one oxide, however, which appears superior to all others, viz., the oxides of manganese which are not sesquioxide. These oxides (Mn_3O_4 and MnO_2) evolve ammonia at a low temperature. From 130°C . to 200°C . most of the ammonia is evolved, and at 325°C . is completely evolved by these oxides. The percentage yield of chlorine by these oxides is one and a half time that of the monoxide of nickel and others. For these and other reasons I think they will hold their place in the new process as they have in the old process of Leblanc.

Peroxides of the composition M_3O_4 , MO_2 may be used with advantage both for the evolution of the ammonia, and afterwards for the chlorine on the passage of air, and for the evolution of the hydrochloric acid on the passage of steam at the low temperature employed.

The workman would keep the temperature below 350°C . during the evolution of the ammonia, which may be done by a mercurial thermometer placed in the door of the retort. Other heavy oxides, salts, &c., require a much higher temperature for the evolution of the ammonia and chlorine.

When all the chlorine or hydrochloric acid is evolved, the residue is equivalent when reduced to the oxide with which we started, and will give the equivalent of ammonia as at first when heated with ammoniac chloride, and from this point the round of operations goes on continually.

The apparatus required would be a Stourbridge fire-clay retort, or other suitable furnace or retort, heated by gas or preferably by a self-feeding coke furnace. These retorts may be worked in series and connected with pipes leading to the ammonia-absorbing plant, the hydrochloric condensing chambers, and the bleaching powder chambers. They should also be connected with an exhaustor or blower for the passage through them of air or steam when chlorine or hydrochloric acid was required.

The residual oxides left after the complete evolution of the chlorine or hydrochloric acid would need washing at intervals from common salt and when manganese has been the oxide used; they exist chiefly as sesquioxide of manganese, and before the charge of ammoniac chloride is added they must be reduced. This may be done by heating them with charcoal or small coal, or, better, by passing the gases from the coke or other furnace used over them, when they will no longer decompose the ammonia when used for the next round of operations.

The lime now used is thus saved, the ammonia and chlorine fully recovered, and reagents for this purpose recovered for use over and over again continually; and this at no other cost than the labour and fuel employed (which is small) and the wear and tear of retorts.

By this development of the ammonia-soda process the old process of Leblanc has lost its last remaining prop.

TUESDAY, SEPTEMBER 11.

The following Report and Papers were read:—

1. *Third Report of the Committee for investigating Isomeric Naphthalene Derivatives.*—See Reports, p. 96.

2. *Note on the Molecular Weight of Caoutchouc and other Colloids.*
By Dr. J. H. GLADSTONE, F.R.S., and W. HIBBERT, F.I.C.

While investigating the chemical and physical properties of caoutchouc the authors had endeavoured to determine by Raoult's method its molecular weight when dissolved in benzene. They found it to be extremely high, although the numbers obtained for caoutchene and hévene (substances of the same ultimate composition) agreed fairly well with what might be anticipated from the formulæ $C_{10}H_{16}$ and $C_{20}H_{32}$. They had subsequently examined the aqueous solutions of other colloid bodies, viz., gum arabic, caramel, albumen, and ferric hydrate, with the result in each case that the molecular weight as determined by Raoult's method is very high. No great reliance was placed upon the actual figures obtained, but they were sufficient to corroborate the conclusion arrived at by Graham long ago, that 'the equivalent of a colloid appears to be always high.'

3. *On some new Silicon Compounds.*
By Professor J. EMERSON REYNOLDS, M.D., F.R.S.

The following substances were exhibited and shortly described:—

and

4. *On some new Thiocarbamide Compounds.*
By Professor J. EMERSON REYNOLDS, M.D., F.R.S.

The following substances were exhibited and shortly described:—

and the trithiocarbamide derivative

5. *Proposed International Standards to control the Analysis of Iron and Steel.* By Professor J. W. LANGLEY.

It is well known that the results of chemical analysis will differ slightly with the methods employed and with the personal peculiarities of the operator. This latter might be called the 'personal equation' of the analyst. These causes of variation become of great importance in all investigations where minute quantities of foreign

bodies have to be sought in large amounts of a compound or mixture, such as are all samples of commercial iron and steel. In this class of analyses the percentages of carbon and phosphorus may be as low as 0.15 per cent. and 0.01 per cent. respectively, and yet these small amounts will have quite marked effects in the steel which contains them.

In order to bring about a greater uniformity of analysis in the countries which are the principal producers and users of iron and steel, it is proposed to prepare a quantity of samples which shall be absolutely identical and to distribute them to properly qualified analysts in those countries, who will then analyse them and will interchange reports of their results with each other.

By the above plan there will be in each country participating in the work a quantity of metal identical with that in the other countries, and which has been analysed with the utmost care by a considerable body of chemists, so that its composition may be said to be known authoritatively and beyond dispute, and which will thus constitute international standards.

The standards so obtained will serve two important purposes. First, they will show, in the course of their preparation, the relative agreement in processes and results habitually arrived at by the chemists of different countries. Second, these standards being distributed to certain custodians, it may be possible to furnish small portions of them to chemists who may make application for the purpose of checking their individual work and obtaining a measure of their accuracy. Also, as new analytical methods are constantly being invented, it will be of great advantage to have a standard metal on which to test them.

The details of the best method of securing the above ends should be the work of a committee.

Professor Hermann Wedding, of Berlin, and Professor Richard Åkerman, of Stockholm, and myself have already considered the general plan, and have given provisional assent to it and to the following suggestions:—

First. The analysis shall be made for total carbon and for phosphorus. This is all which it is advisable to demand, but other elements may be added at the wish of any analysts for the samples in their hands only.

Second. The samples shall be of the following composition (or temper) in carbon, as nearly as is practicable.

Carbon = 1.3% 0.8% 0.4% 0.15%

and all the other elements shall be kept down to the customary proportions for steel of medium quality.

Third. The samples shall be in the form of drillings, uniformly and carefully mixed, and quantities not less than forty kilogrammes for each temper: this would mean not less than 160 kilos. for the whole.

Fourth. These samples shall be equally divided and sent under seal to properly accredited persons in Sweden, Germany, England, and the United States.

Fifth. The analyses shall be made in each country independently, and the report of the results obtained shall be sent to each of the proper representatives of the other countries participating in this plan.

Sixth. If there should be an important disagreement in these reports it shall then be the duty of the parties to this agreement to appoint an international committee to whom the whole subject shall be referred. If, however, the reports differ only slightly then the average of all the reports shall be deemed the true composition of the international iron and steel standards.

6. *On the Action of Light on Water Colours.*

By ARTHUR RICHARDSON, *Ph.D.*

In this paper the author discusses the effect of light on colours, and draws attention to the very important part played by moisture in assisting their decomposition. Unstable colours are divided into two groups:—

1st. Those which bleach by oxidation under the combined influence of light,
1888.

τ τ

air, and moisture. 2nd. Those on which light exerts a reducing action, which is independent of the air, and in some cases takes place in the absence of moisture.

Cadmium yellow, cadmium orange, king's yellow, crimson lake, and indigo are placed in the first group; these are bleached by light, under the conditions above stated, but are permanent in an atmosphere of carbon dioxide, or in dry air. The colours of the second group include Prussian blue, vermilion, chrome yellow, &c. Prussian blue fades slowly in moist air—much more readily, however, in an atmosphere of carbon dioxide; but it is permanent in dry air. Mixed with cadmium yellow, Prussian blue gives a green which is very sensitive to light if moisture is present: permanent, however, in dry air. Vermilion is shown to fade in dry and moist air; also in an inert atmosphere like carbon dioxide. With cadmium yellow, vermilion forms an orange which blackens in moist air in a few hours, though in dry air light is without action on it. The author condemns as unsafe those pigments which fade in dry air, and shows that the greater number of paints are stable in sunlight, provided moisture is absent.

7. *Further Researches on the Pyrocresols.* By Dr. WILLIAM BOTT, F.O.S., and J. BRUCE MILLER, F.I.C.

In a paper submitted to the Chemical Section of the Association last year by Professor Schwarz and W. Bott the properties and a number of derivatives of the three isomeric pyrocresols, $C_{15}H_{14}O$, were described. Since then experiments have been made to ascertain the precise chemical nature of the reduction products of α -pyrocresol. The products just referred to had been found to consist of a mixture of paraffins, and a hydrocarbon, $C_{15}H_{32}$, had been isolated from them.

The reductions both with hydriodic acid and zinc dust have been repeated on a larger scale and at a lower temperature, with a view of obtaining an intermediate compound of an aromatic nature. No such product could, however, be obtained, the reaction invariably giving rise to formation of paraffins only. The investigation of these paraffins is not yet completed, but we expect to be able to publish the details before long, as well as the results of further study regarding the replacement of the oxygen atom in pyrocresol by chlorine by means of phosphorus pentachloride. The present paper only treats of a number of new derivatives of α -pyrocresol which have been prepared during the course of the main investigation.

Trichlor- α -pyrocresol, $C_{15}H_{11}Cl_3O$, is obtained by the protracted action of chlorine upon a solution of α -pyrocresol in chloroform or carbon tetrachloride and repeatedly recrystallising the product from boiling benzene. It forms a white bulky mass consisting of very fine needles, which under the microscope are resolved into pretty and characteristic aggregates of thin, transparent, flat prisms or bars. The substance is insoluble in water, alcohol, ether, acetic acid; more soluble in chloroform and carbon tetrachloride, and readily soluble in boiling benzene. The melting-point is exceptionally high, but cannot be exactly determined, as the body melts very gradually, first showing signs of fusion about 225° .

Tetra-amido- α -pyrocresol oxide, $C_{15}H_8(NH_2)_4O_2$, has been prepared by reduction with tin under pressure of tetra-nitro- α -pyrocresol oxide suspended in a mixture of glacial acetic and hydrochloric acid. It is a greenish yellow powder, slightly soluble in water, sparingly soluble in alcohol and ether, and almost insoluble in benzene. The salts are soluble in water, and with sodium hypochlorite give a dark reddish-brown coloration. A double platinum chloride has also been prepared. The melting-point appears to lie considerably above 300° .

The amido-compound can be diazotised and the diazo salts obtained react with phenols. Experiments in this direction were made with oxy-quinoline, resorcin, thymol salicylic acid, cresol, phenol, α - and β -naphthol. The derivative obtained with β -naphthol has been examined more closely and would represent the first colouring matter obtained from pyrocresol. It is obtained by adding an alkaline solution of β -naphthol to a diazotised acid solution of the amido-compound and forms a dark red precipitate insoluble in water but soluble in ether, alcohol, chloroform, and benzene. With strong sulphuric acid it gives a very characteristic and beautiful reaction, dissolving in the concentrated acid with a deep, greenish

blue colour, which upon gradual dilution with water slowly changes to a red, the colouring matter being reprecipitated in red flakes by excess of water. Although insoluble in water it is slightly soluble in dilute sulphuric and also in acetic acid, and silk may be dyed a fine crimson shade in baths acidified with these acids. If the colouring matter is dissolved in strong sulphuric acid and a single drop of concentrated nitric added to the solution the colour immediately changes from a dark blue to a claret shade. The latter reaction and the behaviour of the sulphuric acid solution upon diluting with water are two equally characteristic and delicate tests.

The action of alkaline-reducing agents, viz., of sodium ethylate and methylate, sodium amalgam and ammonium sulphide in alcoholic solution upon tetra-nitro- α -pyrocresol oxide, gives rise to the formation of varying quantities of amido- and of azo-compounds. The action of ammonium sulphide is particularly interesting. If a small quantity of the nitro-compound is heated with alcohol and a few drops of ammonium sulphide, the supernatant liquid assumes a reddish-brown colour, and upon the addition of hydrochloric acid and warming a red precipitate is formed, insoluble in water, but soluble in chloroform, alcohol, ether, benzene, and acetone with a reddish-violet colour. It is practically insoluble in carbon disulphide, and thus may be separated from any admixture of sulphur. With strong sulphuric acid it yields a yellowish solution, and upon diluting the colouring matter separates unchanged as a red precipitate. It dyes silk a reddish shade, but only in strongly acid baths.

By protracted treatment of the nitro-compound with excess of alcoholic ammonium sulphide a solution is obtained which with hydrochloric acid no longer yields a red colour. On adding water a yellow precipitate is formed, insoluble in hydrochloric acid, slightly soluble in cold water, and a little more soluble in hot water, the hot aqueous solution dyeing silk a fine yellow. The colouring matter is only slightly soluble in alcohol, ether, chloroform, and almost insoluble in benzene.

We have not had sufficient time to determine the composition of the red and yellow colouring matters which have only quite recently been prepared. From their mode of formation it would appear that the red body is an azoxy- or else oxyazo-derivative, whilst the yellow substance would be azo-pyrocresol oxide; still this is a mere conjecture, and their composition may turn out to be of a more complex nature.

It is proposed to apply the above reactions to the β - and γ -isomerides of pyrocresol, and, by sulphonating or otherwise, to prepare the colouring matters in a pure and soluble condition, and to study their special qualities as dyes. Experiments are also in progress to obtain direct nitro-substitution products of the pyrocresols, of which only the nitrated oxides are known, and to prepare the phenols corresponding to the sulphonic acids.

Of nitrated derivatives of the pyrocresols only the tetra-nitro-compounds of the respective oxides had been obtained, no intermediate product being known. A dinitro- α -pyrocresol oxide, $C_{15}H_{10}(NO_2)_2O_2$, has, however, been lately prepared by treating α -pyrocresol oxide with cold concentrated nitric acid and extracting the product with boiling alcohol to remove unaltered oxide. It forms yellowish-white crystals melting at about 235° .

The main work being still progressing, little can be added to the views expressed in the previous paper on the structure of the pyrocresols. The fundamental question as to the position of the oxygen atom in the molecule of pyrocresol, $C_{15}H_{14}O$, thus still remains open. An argument in favour of the existence of the carbonyl group in the molecule of α -pyrocresol at least might be found in the formation of the reduction product $C_{15}H_{32}$; but we have formerly stated our reasons against this supposition. Still adhering to the belief that α -pyrocresol contains the oxygen atom linked to two carbon atoms, the production of the compound $C_{15}H_{32}$ necessitates the assumption of a closed ring instead of two separate chains; thus:

SECTION C.—GEOLOGY.

PRESIDENT OF THE SECTION—Professor W. BOYD DAWKINS, M.A., F.R.S.,
F.G.S., F.S.A.

THURSDAY, SEPTEMBER 6.

The PRESIDENT delivered the following Address:—

IN taking the chair occupied twenty-four years ago in this place by my honoured master, Professor Phillips, I have been much perplexed as to the most fitting lines on which to mould my Address. It was open to me to deal with the contributions to our knowledge since our last meeting in Manchester in such a manner as to place before you an outline of our progress during the last twelve months. But this task, difficult in itself, is rendered still more so by the special circumstances of this meeting, attended, as it is, by so large a number of distinguished geologists, assembled from nearly every part of the world for the purposes of the Geological Congress. It would be presumptuous of me, in the presence of so many specialists, to attempt to summarise and co-ordinate their work. Indeed, we stand too near to it to be able to see the true proportions of the various parts. I will merely take this opportunity of offering to our visitors, in the name of this section and of English geologists in general, a hearty welcome to our shores, feeling that not only will our science be benefited enormously by the simplification of geological nomenclature, but that we ourselves shall derive great advantage by a closer personal contact than we have enjoyed hitherto.

Our science has made great strides during the last twenty-four years, and she has profited much from the great development of her sisters. The microscopic analysis of the rocks has opened out a new field of research, in which physics and chemistry are in friendly rivalry, and in which fascinating discoveries are being made almost day by day as to metamorphism, and the crushing and shearing forces brought to bear upon the cooling and contracting crust while the earth was young. The deep-sea explorations have revealed the structure and the deposits of the ocean abysses, and the depths supposed to be without life, like the fabled deserts in the interior of Africa, are now known to teem with varied forms glowing with the richest colours. From a comparison of these deposits with the stratified rocks we may conclude that the latter are marginal, and deposited in depths not greater than 1,000 fathoms, or the shore end of the Globigerina ooze, and most of them at a very much less depth, and that consequently there is no proof in the geological record of the ocean depths having ever been in any other than their present places.

In North America the geological survey of the Western States has brought to light an almost unbroken series of animal remains, ranging from the Eocene down to the Pleistocene Age. In these we find the missing links in the pedigree of the Horse, and sufficient evidence of transitional forms to cause Professor Flower to restore to its place in classification the order Ungulata of Cuvier. These may be expected to occupy the energies of our kinsmen on the other side of the Atlantic for many years, and to yield further proof of the truth of the doctrine of evolution. The use of this word reminds me how much we have grown since 1864, when evolution was under discussion, and when biological, physical, and geological

laboratories could scarcely be said to have existed in this country. Truly may the scientific youth of to-day make the boast—

‘*Ἡμεῖς μὲν πατέρων μὲν ἀμείνονες εὐχομεθ εἶναι—*

‘We are much better off than our fathers were,’ while we, the fathers, have the poor consolation of knowing that when they are fathers their children will say the same of them. There is reason to suppose that our science will advance more swiftly in the future than it has in the past, because it has more delicate and precise methods of research than it ever had before, and because its votaries are more numerous than they ever were.

In 1864 the attention of geologists was mainly given to the investigations of the later stages of the Tertiary Period. The bent of my pursuits inclines me to revert to this portion of geological inquiry, and to discuss certain points which have arisen during the last few years in connection with the classificatory value of fossils, and the mode in which they may be best used for the co-ordination of strata in various parts of the world.

The principle of homotaxy, first clearly defined by Professor Huxley, has been fully accepted as a guiding principle in place of synchronism or contemporaneity, and the fact of certain groups of plants and animals succeeding one another in a definite order, in countries remote from each other, is no longer taken to imply that each was living in the various regions at the same time, but rather, unless there be evidence to the contrary, that they were not. While, however, there is a universal agreement on this point among geologists, the classificatory value of the various divisions of the vegetable and animal kingdoms is still under discussion, and, as has been very well put by my predecessor in this chair at Montreal, sometimes the evidence of one class of organic remains points in one direction, while the evidence of another class points in another and wholly different direction as to the geological horizon of the same rocks. The Flora, put into the witness-box by the botanist, says one thing, while the Mollusca or the Vertebrata say another thing in the hands of their respective counsel. There seems to be a tacit assumption that the various divisions of the organic world present the same amount of variation in the rocks, and that consequently the evidence of every part of it is of equal value.

It will not be unprofitable to devote a few minutes to this question, premising that each case must be decided on its own merits, without prejudice, and that the whole of the evidence of the flora and fauna must be considered. We will take the flora first.

The cryptogamic flora of the later Primary rocks shows but slight evidence of change. The forests of Britain and of Europe generally, and of North America, were composed practically of the same elements—*Sigillaria*, *Calamites*, and conifers allied to the Ginkho—throughout the whole of the Carboniferous (16,336 feet in thickness in Lancashire and Yorkshire) and Devonian rocks, and do not present greater differences than those which are to be seen in the existing forests of France and Germany. They evidently were continuous both in space and time, from their beginning in the Upper Silurian to their decay and ultimate disappearance in the Permian Age. This disappearance was probably due to geographical and climatic changes, following the altered relations of land to sea at the close of the Carboniferous Age, by which Secondary plants, such as *Voltzia* and *Walchia*, were able to find their way by migration from an area hitherto isolated. The Devonian formation is mapped off from the Carboniferous, and this from the Permian, but to a slight degree by the flora, and nearly altogether by the fauna. While the fauna exhibits great and important changes, the flora remained on the whole the same.

The forests of the Secondary Period, consisting of various conifers and cycads, also present slight differences as they are traced upwards through the Triassic and Jurassic rocks, while remarkable and striking changes took place in the fauna, which mark the division of the formations into smaller groups. As the evidence stands at present, the cycads of the Lias do not differ in any important character from those of the Oölites or the Wealden, and the *Salisburia* in Yorkshire in the Liassic Age is very similar to that of the Island of Mull in the Early Tertiary, and to that (*Salisburia adiantifolia*) now living in the open air in Kew Gardens.

Nor do we find evidence of greater variation in the dicotyledonous forests, from their first appearance in the Cenomanian stage of the Cretaceous rocks of Europe and America, through the whole of the Tertiary Period down to the present time. In North America the flora of the Dakota series so closely resembles the Miocene of Switzerland that Dr. Heer had no hesitation in assigning it in the first instance to the Miocene Age. It consists of more than one hundred species, of which about one-half are closely allied to those now living in the forests of North America—sassafras, tulip, plane, willow, oak, poplar, maple, beech, together with *Sequoia*, the ancestor of the giant redwood of California. The first Palms also appear in both continents at this place in the Geological record.

In the Tertiary Period there is an unbroken sequence in the floras, as Mr. Starkie Gardner has proved, when they are traced over many latitudes, and most of the types still survive at the present day, but slightly altered. If, however, Tertiary floras of different ages are met with in one area, considerable differences are to be seen, due to progressive alterations in the climate and altered distribution of the land. As the temperature of the Northern Hemisphere became lowered the tropical forests were pushed nearer and nearer to the equator, and were replaced by plants of colder habit from the northern regions, until ultimately, in the Pleistocene Age, the Arctic plants were pushed far to the south of their present habitat. In consequence of this Mr. Gardner concludes that 'it is useless to seek in the Arctic regions for Eocene floras as we know them in our latitudes, for during the Tertiary Period the climatic conditions of the earth did not permit their growth there. Arctic fossil floras of temperate and therefore Miocene aspect are in all probability of Eocene age, and what has been recognised in them as a newer or Miocene facies is due to their having been first studied in Europe in latitudes which only became fitted for them in Miocene times. When stratigraphical evidence is absent or inconclusive, this unexpected persistence of plant types or species throughout the Tertiaries should be remembered, and the degrees of latitude in which they are found should be well considered before conclusions are published respecting their relative age.'

This view is consistent with that held by the leaders in botany, Hooker, Dyer, Saporta, Dawson, and Asa Gray—whose recent loss we so deeply deplore—that the North Polar region is the centre of dispersal, from which the deciduous Dicotyledons spread over the Northern Hemisphere. If it be true—and I, for one, am prepared to accept it—it will follow that for the co-ordination of the subdivisions of the Tertiary strata in various parts of the world the plants are uncertain guides, as they have been shown to be in the case of the Primary and Secondary rocks. In all cases where there is a clash of evidence, such as in the Laramie lignites, in which a Tertiary flora is associated with a Cretaceous fauna, the verdict in my opinion must go to the fauna. They are probably of the same geological age as the deposit at Aix-la-Chapelle.

I would remark further, before we leave the floras behind us, that the migration of new forms of plants into Europe and America took place before the arrival of the higher types in the fauna, after the break-up of the land at the close of the Carboniferous period, and after the great change in geography at the close of the Neocomian. The Secondary plants preceded the Secondary vertebrates by the length of time necessary for the deposit of the Permian rocks, and the Tertiary plants preceded the Tertiary vertebrates by the whole period of the Upper Cretaceous.

Let us now turn to the fauna.

Professor Huxley, in one of his many addresses which have left their mark upon our science, has called attention to the persistence of types revealed by the study of Palaeontology, or, to put it in other words, to the singularly little change which the ordinal groups of life have undergone since the appearance of life on the earth. The species, genera, and families present an almost endless series of changes, but the existing orders are for the most part sufficiently wide, and include the vast series of fossils without the necessity of framing new divisions for their reception. The number of these extinct orders is not equally distributed through the animal kingdom. Taking the total number of orders at 108, the number of extinct orders

in the Invertebrata amounts only to 6 out of 88, or about seven per cent., while in the Vertebrates it is not less than 12 out of 40, or 30 per cent. These figures imply that the amount of ordinal change in the fossil Vertebrates stands to that in the Invertebrata in the ratio of 30 to 7. This disproportion becomes still more marked when we take into account that the former had less time for variation than the latter, which had the start by the Cambrian and Ordovician Periods. It follows also that as a whole they have changed faster.

The distribution of the extinct orders in the animal kingdom, taken along with their distribution in the rocks, proves further that some types have varied more than others, and at various places in the geological record. In the Protozoa, Porifera, and Vermes there are no extinct orders; among the Coelenterates one: the Rugosa; in the Echinodermata three: Cystideans, Edriasterida, and Blastoidea; in the Arthropoda two: the Trilobita and Eurypterida. All these, with the solitary exception of the obscure order Rugosa, are found only in the Primary rocks. Among the Pisces there is none; in the Amphibia one; the Labyrinthodonts ranging from the Carboniferous to the Triassic Age. Among the Reptilia there are at least six of Secondary age: Plesiosauria, Ichthyosauria, Dicynodontia, Pterosauria, Theriodontia, Deinosauria; in the Aves two: the Saururæ and Odontornithes, also Secondary. In the Mammalia the Amblypoda, Tillodontia, Condylarthra, and Toxodontia represent the extinct orders—the three first Early Tertiary, and the last Pleistocene. It is clear therefore that, while the maximum amount of ordinal variation is presented by the Secondary Reptilia and Aves, all the extinct orders in the Tertiary are Mammalian.

If we turn from the extinct orders to the extinct species, it will also be found that the maximum amount of variation is presented by the plants, and all the animals, excepting the Mammalia, in the Primary and Secondary Periods.

The general impression left upon my mind by these facts is that, while all the rest of the animal kingdom had ceased to present important modifications at the close of the Secondary Period, the Mammalia, which presented no great changes in the Secondary rocks, were, to quote a happy phrase of Professor Gaudry, 'en pleine évolution' in the Tertiary Age. And when, further, the singular perfection of the record allows us to trace the successive and gradual modifications of the Mammalian types from the Eocene to the close of the Pleistocene Age, it is obvious that they can be used to mark subdivisions of the Tertiary Period, in the same way as the reigns of kings are used to mark periods in human history. In my opinion they mark the geological horizon with greater precision than the remains of the lower members of the animal kingdom, and in cases such as that of Pikermi, where typical Miocene forms, such as Deinotheria, are found in a stratum above an assemblage of marine shells of Pleiocene age, it seems to me that the Mammalia are of greater value in classification than the Mollusca, some of the species of which have been living from the Eocene down to the present day.

Yet another important principle must be noted. The fossils are to be viewed in relation to those forms now living in their respective geographical regions. The depths of the ocean have been where they are now since the earliest geological times, although continual geographical changes have been going on at their margins. In other words, geographical provinces must have existed even in the earlier geological periods, although there is reason to believe that they did not differ so much from each other as at the present day. It follows from this that the only just standard for comparison in dealing with the fossils, and especially of the later rocks, is that which is offered by the fauna and flora of the geographical province in which they are found. The non-recognition of this principle has led to serious confusion. The fauna, for example, of the Upper Sivalik Formation has been very generally viewed from the European standpoint and placed in the Miocene, while, judged by the standpoint of India, it is really Pleiocene. A similar confusion has followed from taking the Miocene flora of Switzerland as a standard for the Tertiary flora of the whole of the Northern Hemisphere.

It now remains for us to see how these principles may be applied to the co-ordination of Tertiary strata in various parts of the world. In 1880 I proposed a classification of the European Tertiaries, in which, apart from the special cha-

racteristic fossils of each group, stress was laid on the gradual approximation of various groups to the living Mammalia. The definitions are the following:—

DIVISIONS.	CHARACTERISTICS.
1. Eocene, or that in which the higher Mammalia (Eutheria) now on the earth were represented by allied forms belonging to existing orders and families. Oligocene.	Extinct orders. Living orders and families. No living genera.
2. Miocene, in which the alliance between fossil and living Mammals is closer than before.	Living genera. No living species.
3. Pleiocene, in which living species of Mammals appear.	Living species few. Extinct species predominant.
4. Pleistocene, in which living species of Mammals preponderate.	Living species abundant. Extinct species present. Man present.
5. Prehistoric, or that period outside history in which Man has multiplied exceedingly on the earth and introduced the domestic animals.	Man abundant. Domestic animals present. Wild Mammals in retreat. One extinct Mammal.
6. Historic, in which the events are recorded in history.	Records.

These definitions are of more than European significance. The researches of Leidy, Marsh, and Cope prove that they apply equally to the Tertiary strata of North America. The Wasatch Bridger and Uinta strata contain representatives of the orders Cheiroptera and Insectivora, the sub-orders Artio- and Perissodactyla, and the families Vespertilionidæ and Tapiridæ; but no living genera.¹ The Mammalia are obviously in the same stage of evolution as in the Eocenes of Europe, although there are but few genera, and no species common to the two.

The White River and Loup Fork Groups present us with the living genera *Sciurus*, *Castor*, *Hystrix*, *Rhinoceros*, *Dicotyles*, and others; but no living species, as is the case with the Miocenes of Europe. In the Pleiocenes of Oregon the first living species appear, such as the Beaver, the Prairie Wolf, and two Rodents (*Thomomys clusius* and *T. talpoides*), while in the Pleistocene river deposits and caves, from Eschscholtz Bay in the north to the Gulf of Mexico in the south, there is the same grouping of living with extinct species as in Europe, and the same evidence in the glaciated regions that the Mammalia occupied the land after the retreat of the ice.

If we analyse the rich and abundant fauna yielded by the caves and river deposits both of South America and of Australia, it will be seen that the Pleistocene group in each is marked by the presence of numerous living species in each, the first being remarkable for their gigantic extinct Edentata, and the second for their equally gigantic extinct Marsupials.

The admirable work of Mr. Lydekker allows us also to see how these definitions apply to the fossil Mammalia of India. The Miocene fauna of the lower Sivaliks has yielded the living genera *Rhinoceros* and *Manis*, and no living species.

The fauna of the Upper Sivaliks, although it has only been shown, and that with some doubt, to contain one living Mammal, the Nilghai (*Boselaphus tragocamelus*), stands in the same relation to that of the Oriental Region, as that of the Pleiocenes of Europe to that of the Palearctic Region, and is therefore Pleiocene.

¹ The genus *Vesperugo* has not been satisfactorily determined.—Cope, *Report of Geol. Survey of the Territories. Tertiary Vertebrata*, I., 1884.

And lastly, the Narbada formation presents us with the first traces of Palæolithic Man in India in association with the living one-horned Rhinoceros, the Nilghai, the Indian Buffalo, two extinct Hippopotami, Elephants, and others, and is Pleistocene.

It may be objected to the Prehistoric and Historic divisions of the Tertiary Period that neither the one nor the other properly falls within the domain of Geology. It will, however, be found that in tracing the fauna and flora from the Eocene downwards to the present day there is no break which renders it possible to stop short at the close of the Pleistocene. The living plants and animals were in existence in the Pleistocene Age in every part of the world which has been investigated. The European Mollusca were in Europe in the Pleistocene Age. The only difference between the Pleistocene fauna, on the one hand, and the Prehistoric, on the other, consists in the extinction of certain of the Mammalia at the close of the Pleistocene Age in the Old and New Worlds, and in Australia. The Prehistoric fauna in Europe is also characterised by the introduction of the ancestors of the present domestic animals, some of which, such as the Celtic shorthorn (*Bos longifrons*), sheep, goat, and domestic hog, reverted to a feral condition, and have left their remains in caves, alluvia, and peat-bogs over the whole of the British Isles and the Continent. These remains, along with those of Man in the neolithic, bronze, and iron stages of culture, mark off the Prehistoric from the Pleistocene strata. There is surely no reason why a cave used by palæolithic Man should be handed over to the geologist, while that used by men in the Prehistoric Age should be taken out of his province, or why he should be asked to study the lower strata only in a given section, and leave the upper to be dealt with by the archæologist. In these cases the ground is common to geology and archæology, and the same things, if they are looked at from the standpoint of the history of the earth, belong to the first, and, if from the standpoint of the history of Man, to the second.

If, however, there be no break of continuity in the series of events from the Pleistocene to the Prehistoric ages, still less is there in those which connect the Prehistoric with the period embraced by history. The historic date of a cave or of a bed of alluvium is as clearly indicated by the occurrence of a coin as the geological position of a stratum is defined by an appeal to a characteristic fossil. The gradual unfolding of the present order of things from what went before compels me to recognise the fact that the Tertiary Period extends down to the present day. The Historic Period is being recorded in the strata now being formed, exactly in the same way as the other divisions of the Tertiary have left their mark in the crust of the earth, and history is incomplete without an appeal to the geological record. In the masterly outline of the destruction of Roman civilisation in Britain the historian of the English Conquest was obliged to use the evidence, obtained from the upper strata, in caves which had been used by refugees from the cities and villas; and among the materials for the future history of this city there are, to my mind, none more striking than the proof, offered by the silt in the great Roman bath, that the resort of crowds had become so utterly desolate and lonely in the ages following the English Conquest as to allow of the nesting of the wild duck.

I turn now to the place of Man in the geological record, a question which has advanced but little since the year 1864. Then, as now, his relation to the glacial strata in Britain was in dispute. It must be confessed that the question is still without a satisfactory answer, and that it may well be put to 'a suspense account.' We may, however, console ourselves with the reflection that the River-drift Man appears in the Pleistocene strata of England, France, Spain, Italy, Greece, Algiers, Egypt, Palestine, and India along with Pleistocene animals, some of which were pre-glacial in Britain. He is also proved to have been post-glacial in Britain, and was probably living in happy, sunny, southern regions, where there was no ice, and therefore no glacial period, throughout the Pleistocene Age.

It may further be remarked that Man appears in the geological record where he might be expected to appear. In the Eocene the Primates were represented by various Lemuroids (*Adapis*, *Necrolemur*, and others) in the Old and New Worlds. In the Miocene the Simiads (*Dryopithecus*, *Pliopithecus*, *Oreopithecus*) appear in Europe, while Man himself appears, along with the living species of Mammalia, in the Pleistocene Age, both in Europe and in India.

The question of the antiquity of Man is inseparably connected with the further question: 'Is it possible to measure the lapse of geological time in years?' Various attempts have been made, and all, as it seems to me, have ended in failure. Till we know the rate of causation in the past, and until we can be sure that it has been invariable and uninterrupted, I cannot see anything but failure in the future. Neither the rate of the erosion of the land by sub-aërial agencies, nor its destruction by oceanic currents, nor the rate of the deposit of stalagmite or of the movement of the glaciers, have as yet given us anything at all approaching a satisfactory date. We only have a sequence of events recorded in the rocks, with intervals the length of which we cannot measure. We do not know the exact duration of any one geological event. Till we know both, it is surely impossible to fix a date, in terms of years, either for the first appearance of Man or for any event outside the written record. We may draw cheques upon 'the bank of force' as well as 'on the bank of time.'

Two of my predecessors in this chair, Dr. Woodward and Professor Judd, have dealt with the position of our science in relation to Biology and Mineralogy. Professor Phillips in 1864 pointed out that the later ages in Geology and the earlier ages of mankind were fairly united together in one large field of inquiry. In these remarks I have set myself the task of examining that side of our science which looks towards History. My conception of the aim and results of Geology is, that it should present a universal history of the various phases through which the earth and its inhabitants have passed in the various periods, until ultimately the story of the earth, and how it came to be what it is, is merged in the story of Man and his works in the written records. Whatever the future of Geology may be, it certainly does not seem likely to suffer in the struggle for existence in the scientific renaissance of the nineteenth century.

The following Papers were read:—

1. *Further Note on the Midford Sands.*¹ By HORACE B. WOODWARD, F.G.S.

[Communicated by permission of the Director-General of the Geological Survey.]

The term Midford Sands, introduced in 1871 by Professor Phillips, has been accepted by many geologists because it avoided the confusion that had arisen from the use by some authorities of the term Inferior Oolite Sands, and by others of Upper Lias Sands.

At Midford the upper portion of the Inferior Oolite (zone of *Ammonites Parkinsoni*) rests directly on the Sands, whereas in other parts of Somersetshire, in Dorsetshire and Gloucestershire, the lower portion of the Inferior Oolite (comprising the zones of *A. Humphriesianus* and *A. Murchisonæ*) is present above the Sands. In the absence of palæontological evidence, it has been questioned whether the Midford Sands are really equivalent to the Sands in other parts of the south-west of England. Hence other local names, e.g., the Yeovil and Bridport Sands, and the Cotteswold Sands, have been introduced.

Regarding the zone of *Ammonites opalinus* and the Gloucestershire Cephalopoda-bed as a portion of the Cotteswold Sands, there is no doubt about their correlation with the Sands of Bridport and Yeovil. Two species of *Ammonites* (*A. striatulus* and *A. aalensis*) have been obtained by the Rev. H. H. Winwood from the Midford Sands. The latter of these species was recorded by myself, on the authority of Mr. Etheridge, in 1876, but its occurrence has been overlooked. More recently I have seen in the William-Smith Collection in the British Museum an *Ammonite* from the Coal-canal at Midford; and this has been identified by Mr. Etheridge and Mr. R. B. Newton as very near to, if not identical with, *A. Levesquei*, a species recorded by Dr. Lycett from the Gloucestershire Cephalopoda-bed. These species show that the Midford Sands belong to the same general horizon as the Sands of Gloucestershire and Dorsetshire, so that there is no adequate

¹ A previous Note on the Midford Sands was published in the *Geol. Mag.* 1872, p. 513.

reason for discarding the name Midford Sands. If the beds near Bath have not proved so fossiliferous as those in other localities, there is no reason why they should remain so; for in Dorsetshire there are many sections where the beds appear barren, in close proximity with other exposures that yield an abundant fauna.

2. *The Relations of the Great Oolite to the Forest Marble and Fuller's-earth in the South-west of England.* By HORACE B. WOODWARD, F.G.S.

[Communicated by permission of the Director-General of the Geological Survey.]

The southerly attenuation of the Great Oolite, and its absence in Dorsetshire, have been generally attributed to lateral changes in the strata—it being considered that the Great Oolite is mainly replaced by Forest Marble (which has been stated to increase in thickness southwards), and perhaps in part by the Fuller's-earth.

In Gloucestershire the Great Oolite and Forest Marble are so interblended that there is no real line of demarcation. At Bradford-on-Avon this is not the case: the surface of the Great Oolite, with its clusters of *Apiocrinus*, indicates a pause in deposition, and we have locally a good line of division between this formation and the Bradford Clay, which is a subordinate portion of the Forest Marble. Southwards the Bradford Clay horizon extends to the Dorsetshire coast, but the Great Oolite is no longer found, and we see no evidence of the Crinoid growth *in situ*. The estimated thickness of the Forest Marble in Dorsetshire has been much exaggerated, and the evidence furnished by the persistence of the Bradford Clay is opposed to the view that the Great Oolite is replaced in any way by the Forest Marble.

In Oxfordshire and Gloucestershire the Great Oolite and the Stonesfield Slate merge downwards into the Fuller's-earth with no marked stratigraphical division, and this is the case as far as Lansdown, near Bath. Northwards the Fuller's-earth is much attenuated, and near Chipping Norton it rests on a higher stage of the Inferior Oolite than we find in the Cotteswold Hills, as if in the former area the conditions attending the deposition of Inferior Oolite lingered longer. Rarely do we find any interblending of Inferior Oolite and Fuller's-earth; indeed, we sometimes find indications of local pauses in deposition, marked by annelide burrows, &c. So that on stratigraphical grounds the Fuller's-earth is more intimately connected with the Great Oolite than with the Inferior Oolite.

In Dorsetshire the Fuller's-earth series attains its greatest development in this country, and is separable into Upper and Lower clayey divisions with an intermediate bed of Fuller's-earth Rock. These divisions may be traced northwards to Lansdown and Slaughterford, near Bath, where the Fuller's-earth Rock is present in an attenuated form, and where the Upper Fuller's-earth merges into the base of the Great Oolite.

It is therefore clear that the mass of the Great Oolite is not represented in the Fuller's-earth series of Dorsetshire, although its lower beds may be partially replaced by the Upper Fuller's-earth. The mass of the Great Oolite, therefore, either wedges out abruptly south of Bradford-on-Avon, or has been to some extent denuded. On the whole, it appears probable that the Great Oolite has been denuded—the erosion being local and contemporaneous so far as the Great Oolite series is concerned. The structure of the Forest Marble, with its clay-galls, its current-bedded limestones made up of broken shells and oolitic grains (the latter sometimes in a sandy matrix), favours the notion that it may have been largely derived from previous accumulations; and this opinion was suggested by Dr. Sorby from a microscopical study of some of the beds.

The organic remains of the Fuller's-earth include many species common to the Inferior Oolite and many common to the Great Oolite. Of seventy-two species, obtained during the course of the Geological Survey, fifty-eight are known also in the Great Oolite and forty-two in the Inferior Oolite, a number being common to the two formations. The palæontological evidence therefore coincides with the

stratigraphical, that the Fuller's-earth on the whole is more intimately connected with the Great Oolite than with the Inferior Oolite. For convenience of classification it should therefore be placed with the Great Oolite series.

3. *Note on the Portland Sands of Swindon and elsewhere.*

By HORACE B. WOODWARD, *F.G.S.*

[Communicated by permission of the Director-General of the Geological Survey.]

Attention was drawn to some fresh sections at Swindon and these confirmed the sequence made out by Professor J. F. Blake from somewhat scattered data. The sandy beds that yield the Swindon Stone were originally grouped as 'Portland Sands,' but they clearly belong to the Portland Stone division, as pointed out by Mr. Blake. The basement bed here and at Aylesbury consists of a conglomeratic band containing lydites, a few quartz pebbles, and some derived fossils. The true Portland Sands occur below, and are about 60 feet thick. The sequence is as follows:—

	feet
Portland Stone, with lydite bed at base and in upper part of clay beneath.	
Portland Sands. { 3. Blue and brown clay	19
{ 2. Sandy calcareous rock. Oyster-bed with small acuminate oyster	8
{ 1. Greenish and yellowish sands with huge concretionary masses of calcareous sandstone. The sands merge downwards into	30 to 40
Kimmeridge Clay.	

Comparing the sequence with that at Aylesbury, worked out by Mr. Hudleston, we find the Portland Stone with lydite bed at base resting on the Hartwell Clay. This clay, like the Blue and brown clay (No. 3.) at Swindon, was originally taken to be Kimmeridge Clay, but the former has been shown to be on the horizon of the Middle Portlandian of French geologists; and there is no doubt, on stratigraphical and palæontological grounds, that the clays of Swindon and Hartwell are on the same approximate horizon, and that both belong to the Portland Sands. We have not clear evidence of the sequence beneath the Hartwell Clay at Aylesbury; but a deep well at Stone, in that neighbourhood, showed the presence beneath the Portland Stone of Blue clay, Limestone, Dark sand, and then Blue clay again—this last-named bed being, no doubt, the true Kimmeridge Clay, although detailed measurements are wanting.

Doubtless there is some inconvenience in a term like Portland Sands, when it includes prominent beds of clay like those of Swindon and Hartwell, and when the Portland Stone of Swindon is so largely represented by sand. We might employ the terms Upper and Lower Portlandian were it not that on the Continent a three-fold division has been adopted, and the Lower Portlandian embraces beds that in this country cannot be separated from the Kimmeridge Clay. The Middle Portlandian, as before mentioned, represents our Portland Sands and Hartwell Clay; and Professor Blake has applied the term Bolonian to these Middle and Lower Portlandian beds. On stratigraphical grounds it does not appear possible for us to adopt that term, and on the whole the following grouping appears best adapted for the English strata:—

Upper Portland Beds—Portland, Tisbury and Swindon Stone.

Lower Portland Beds—Portland Sands and Hartwell Clay.

It is true that at Swindon and Hartwell the Lower Portland Beds are more intimately connected, on stratigraphical grounds, with the Kimmeridge Clay than with the Upper Portland Beds; but this is not the case on the Dorsetshire coast, where no conglomeratic band has been met with at the base of the Portland Stone.

4. *On Local Geological Photography.* By OSMUND W. JEFFS.

In this paper the author suggests the desirability of taking steps to secure the formation of a collection of photographic views illustrating the geological features of each county.

Isolated attempts to record local geological features of importance have been made by several provincial societies, amongst others by the Leicester Literary and Philosophical Society, Liverpool Geological Society, Belfast Naturalists' Field Club, Chester Society of Natural Science, the Geological Society of Yorkshire, the Croydon Microscopical and Natural History Society, &c. ; but there is need for some systematic scheme to secure uniformity of action in every district in England.

This could best be done by the appointment under this Association (which is in touch with all centres of scientific activity in the United Kingdom) of officers in each county charged with the arrangement of details and superintendence of local photographic surveys in their respective districts. The results obtained would be duly preserved, recorded, and catalogued by a central officer of the Association, who would give facilities for the purchase and exchange of views.

It is important that the date, name of photographer, and full descriptive details (accompanied by explanatory sketches when necessary) be attached to every picture taken. The suggestions made in the paper are for consideration, and subject to such modification as may be arranged by the Committee or the Officers of Section C.

Photographic records of sections and of other geological features and physio-graphical phenomena are not only invaluable as aids to class-teaching and geological instruction generally, but they will serve to preserve for future reference the details of many exposures of strata and other important landscape features which in course of time, by natural and other agencies, are in danger of becoming obliterated.

5. *Further Notes on the Origin of the Crystalline Schists of Malvern and Anglesey.* By CHARLES CALLAWAY, D.Sc., M.A., F.G.S.

At the meeting of the Association in 1887 the author noticed that in the Malvern Hills the foliation was *zonal*. The igneous rocks, as a shear zone was approached, acquired a parallel structure, and where the zone was penetrated by granite veins hornblende was converted into black mica. In Anglesey also some of the schists resulted from the shearing of igneous rocks, and it was suggested as probable that the limestones of the Older Archæans were endogenous deposits derived from the decomposition of the adjacent rocks.

Subsequent work in the field and cabinet confirmed and enlarged the above results. At Malvern some new shear zones were examined. At one locality diorite interlaced with vertical granite-veins passed, within the breadth of a yard, into a banded gneiss, with a dip of 70°. Both granite and diorite exhibited progressive shearing and mineral change. The granite (binary) passed through the usual stages into muscovite gneiss. These seams were interbanded with a dark schist, consisting mainly of hornblende crystals flattened out, white mica and black mica.

A large series of observations showed that when a complex of granite and diorite was sheared, mica was produced in both. In the diorite either biotite was formed from the hornblende, or muscovite replaced soda-lime felspar. Sometimes both micas were generated in the diorite.

Injection schists were sometimes formed by *infiltration*. Granite and diorite were in contact. Shearing was progressive towards the granite and into it. The diorite near the junction went largely to chlorite and iron-oxide. These passed into the cracks of the crushed granite, and as the latter was progressively sheared they retained their place between the folia of quartz and felspar. Thus a chlorite gneiss was formed. Black mica was sometimes generated in the chlorite, especially round opaque dots (? iron-oxide).

The mica (? sericite) schist of the western spur of Ragged Stone Hill was formed

from diorite. The chemical change was greatest where the shearing reached its maximum. In an intermediate stage the rock was a sort of grit, consisting of parallel seams of felspar fragments immersed in chlorite. Much lime was liberated as carbonate. The percentage of silica rose during the process of schist-making from forty-seven to sixty-five.

In Anglesey additional evidence for the conversion of felsite to mica-schist had been procured. At Porth Nobla a felsitic rock passed into h  lleflinta, which, by shearing, graduated into schists. The granite of Llanfaelog was intrusive in these and other adjacent rocks. The author's time-succession in the older schists of Anglesey could not, of course, be regarded as more than a mineral succession in the light of the new views of metamorphism. The case was different with the Newer Arch  an (? Pebidian) series, in which there was a passage between the hypometamorphic slates and true crystalline schists, the foliation of the latter coinciding with the bedding, which was clearly indicated by bands of grit.

6. *Sketch of the Geology of the Crystalline Axis of the Malvern Hills.*

By CHARLES CALLAWAY, D.Sc., M.A., F.G.S.

This ridge was composed of rocks which had originally been eruptive, but in places they had undergone such important structural and chemical changes that they might fairly be called 'metamorphic.' The original rocks were diorite (several varieties), epidiorite, a binary granite, and felsite. The principal rocks of secondary origin were muscovite gneiss, biotite gneiss, hornblende gneiss, and mica schists, some of these schists being *simple* (formed from one kind of rock), while others were *injection* schists (formed out of veined masses).

In the North Hill massive diorites predominated, but a gneissic structure was frequently produced by pressure. The mass, which culminated in the Worcester-shire Beacon, consisted of diorites with intrusive granite. The granite veins in diorite, accompanied by shearing, gave rise to various gneisses. At the Wych there was a chlorite gneiss, which was a sheared granite, into which chlorite from decomposed diorite had infiltrated. Between here and the Wind's Point the rock was mainly diorite with granite veins, occasionally compressed and sheared. The Herefordshire Beacon was of similar composition, but its eastern spurs consisted of felspathic rocks, some of which, according to Mr. Rutley, were perlitic felsites. These rocks were probably of Uriconian (Newer Arch  an) age, and might perhaps be correlated with the Pebidian of Dr. Hicks.

Granite in masses formed the northern end of Swinyard's Hill; near the southern end it was sheared into mica gneiss, and at the southern extremity, in association with diorite, it formed injection schist. Midsummer Hill was mostly diorite. Ragged Stone Hill was a complex mixture of diorite, granite, felsite, and epidiorite. At the south-eastern spur felsite was sheared into mica schist, while the south-western spur mainly consisted of a mica schist, which could be traced into a diorite. This schist was overlain unconformably by the Hollybush Sandstone (Cambrian). The bulk of the Malvern crystalline rocks were Older Arch  an. The Malvern axis was thus seen to furnish many interesting facts bearing on the origin of the crystalline schists.

7. *Archean Characters of the Rocks of the Nucleal Ranges of the Antilles.*

By Dr. PERSIFOR FRAZER.

During a visit this year to the south-eastern part of the island of Cuba, the speaker had made some examinations of the rocks which form the nucleus of the spurs of the Sierra Maestra, and there is strong reason to believe of the axial range of the entire island and of Jamaica, Santo Domingo, Puerto Rico, and the Windward Islands as well. From the field observations there made, and an examination of the specimens under the microscope, it seems highly probable that these rocks, instead of being igneous extrusions of the Tertiary period and later, are in reality of much earlier date, and may not be entirely volcanic.

The considerations which support this view are—

1. Microscopic analysis shows immense alteration to have taken place, and consequently a very long period to have elapsed.

2. The complexity of the congeries of rocks forbids the hypothesis of their having been derived from one mass. Where this congeries, therefore, is unconformably adjacent to the Tertiary, there can be no reasonable doubt that the crystalline rocks are the elder. This point of view was suggested by Mr. Teall, who would consider the argument valid also for the contact with the Cretaceous, and perhaps older series. It is difficult to see why it should not hold equally good for the contact between these crystalline and the Paleozoic rocks as made out by De Castro near Cienfuegos, &c.

3. The characters of the several associated rocks are those which one finds united in very many Archean regions throughout the world.

4. The products of alteration of these rocks are similar to those which one finds in the districts just alluded to.

5. The chemical peculiarities of the iron ores found in contact with these rocks are similar to those which one finds in the ores of the Archean regions, both in the low percentage of phosphorus and in the pyrite and (more sparingly) chalcopryrite disseminated through the ore, and in other respects.

6. If this nucleal mass had been forced up from the earth's interior in a state of igneous fusion there would not be now (as there are) abundant traces of stratification and structure, implying an original sedimentation.

7. If this mass had resulted from volcanic outflow there must have been contact phenomena, and changes induced on the surfaces of the rocks with which it was brought in contact. No such contact alteration has been observed between these rocks and those of either the Paleozoic, Mesozoic, or Cenozoic groups which in different localities meet them.

8. The direction of the range, considered as a whole, lends support to the hypothesis that it is a fork of the Andes which, diverging from the main axis in Guatemala, traverses the peninsula of Yucatan, and in a symmetrical curve sweeps through the highlands of Cuba and Jamaica, Hayti, Puerto Rico, the Windward Islands, and the N.E. coast of Venezuela. This rim of high land once enclosed the Caribbean as another Mediterranean Sea.

9. The shapes of the hills of this range, produced by weathering, are not those usually visible in regions of volcanic, but rather of metamorphic rocks.

The rocks which furnished the basis for the above conclusions are all, or nearly all, alteration products. In some cases they appeared to be the results of a series of metamorphoses, some of their constituents seeming to pass through cycles of change, ending in the mineral with which the alteration began after a number of intermediate stages. The rocks are Diabases or Diorites, with Epidote, Porphyritic Dolerites, which resemble and have been taken for Syenites; Garnet rock; Actinolite; Felsite and Orthofelsite Porphyry, like that of the South Mountain of South-eastern Pennsylvania, of St. David's Head in Wales, and elsewhere. To these are added Pyrite, and iron ores and crystalline limestone. Copper and manganese ores are not rare, but their relations to the rocks under consideration have not been made out.

NOTE.—A number of the first petrologists of Europe who have examined their slides are disposed to consider the specimens of not later than Paleozoic age, while none are willing to deny that they *may* be earlier.

8. *On a Specimen of Quartz from Australia and Three Specimens of Oligoclase from North Carolina exhibiting curious Optical Properties.*
By Dr. PERSIFOR FRAZER.

Mr. George F. Kunz, Gemmist for Tiffany & Co., of New York city, and reporter on the precious stones of the United States for the United States Geological Survey, desires through me to call attention to these minerals, on the curious optical properties of which a preliminary note appears in the 'American Journal

of Science' for September. Further investigations will be published in succeeding numbers of this journal. The Oligoclase presents an appearance like that seen in devitrified glass, where numbers of small star-like masses appear in the transparent matrix. The quartz, which unfortunately has been superficially polished, exhibits twin structure when viewed along the axis \propto P, the alternate parts of the twin being differentiated by smoky and clear quartz.

In the interior a singular segregation of foreign matter has taken place along the plains of twinning, but in such a manner as to mark the outline of a hexagonal or ditrigonal pyramid.

FRIDAY, SEPTEMBER 7.

The following Report and Papers were read:—

1. *Sixteenth Report on the Erratic Blocks of England, Wales, and Ireland.*
See Reports, p. 101.

2. *On a High Level Boulder-clay in the Midlands.*
By Dr. H. W. CROSSKEY, F.G.S.

3. *On the Extension of the Bath Oolite under London, as shown by a Deep Boring at Streatham.* By W. WHITAKER, B.A., F.R.S.

The attempts to get water from beds deep underground in and near London have done much to reveal the geological structure of that district, and to prove what was before only the theory of the geologist to be a fact, namely, that along part of the valley of the Thames the regular succession of the formations is broken by the occurrence of a mass of older rocks, rising up so as, in some cases, to come next beneath the Gault.

This has been brought about by the underground extension eastward of the great line of disturbance, of which so much is seen at the surface in the west of England, in the great saddleback of the Mendips, in the trough of the South Wales Coal-field, and in the bringing in of coal-fields under Jurassic formations.

Whether the Bath waters have anything to do with this disturbance I cannot say, but we have not yet succeeded in tapping them under London.

Not the least interesting result of the set of experiments in deep boring has been the discovery of beds of Jurassic age in two of the borings, at Meux's Brewery and at Richmond. These beds, though comparatively thin, can be referred with safety to the lower division of the series, or that which is so well developed round Bath, both from their character and from their fossils.

A boring now being made by the Southwark and Vauxhall Water Company at Streatham, a southern part of London, has passed through the following formations, and then, at the depth of 1,081½ feet, has passed at once into Jurassic limestone:—

	feet
Tertiary beds	241½
Chalk	623
Upper Greensand	29
Gault	188

This limestone is hard, compact, for the most part of coarsely oolitic structure and with small fragments of shells. It is almost exactly like some of the Forest Marble of Wiltshire, so much indeed that specimens from the two can hardly be distinguished.

As it is in the two other borings nearest to Streatham that Jurassic rocks, also referred to the Forest Marble, have been found, we may fairly infer the existence of

a continuous sheet of these rocks from the central part of London for some miles southward. How far south we cannot say. We can, however, limit the northerly extension, as in the northern part of London and beyond no Jurassic beds have been found. On the east, too, along the valley of the Thames, they soon end off, though they may extend far beneath the broad tract of the Weald, and perhaps also under some of the bordering chalk tract.

The object of the various borings alluded to has been to get water from the Lower Greensand, which formation comes next beneath the Gault at the outcrop on the south, right through Surrey and Kent. The borings have, however, proved that it thins out underground northward, not reaching so far as London.

The only chance, therefore, of getting water from this formation near London seems to be by tapping some older formation which may come into contact with the Lower Greensand in some part of its underground course, and may be permeable enough to receive and to carry off some of its water. The Jurassic limestone as yet found at Streatham is too compact for this, but the boring will be continued for awhile in the hope of reaching beds of looser texture.

Should the Company, however, feel compelled to abandon the work, it is to be hoped that some means may be taken to carry it on as a scientific experiment, in order to find out what formation comes beneath the Jurassic beds, which, in the two borings that have pierced them, are succeeded by red sandstones and marls of doubtful age, or by undoubted Devonian rocks. We have now another chance of solving an important problem, the question whether Coal Measures occur along the valley of the Thames.

NOTE.—Since this paper was read the boring has been carried through the Jurassic beds, which are only $38\frac{1}{2}$ feet thick, and has entered a set of compact calcareous sandstones, grey and greenish grey, mottled with maroon-colour, probably with beds of clay (specimens of which are not brought up by the boring-tool). These beds are like those of Richmond and of doubtful age—New Red or Old Red?

4. *On the Lower Carboniferous Rocks of Gloucestershire.*

By E. WETHERED, F.G.S., F.C.S., F.R.M.S.

In Gloucestershire there are two coalfields, namely, that of the Bristol and Forest of Dean. The Carboniferous Limestone Series of Gloucestershire were long ago divided by Sir H. De La Beche as follows:

UPPER MIXTURE OF SANDSTONES.

	Clifton feet	Forest of Dean feet
Marls and Limestones	400	146
Central Portion	1,438	480
Lower Shales	500	165
	<hr/> 2,338	<hr/> 791

The author has proposed some detailed alterations with regard to the Bristol coalfield which are stated in the 'Quarterly Journal of the Geological Society' for 1888, p. 187, but the above divisions have been generally accepted under the terms Lower Limestone Shales, Carboniferous Limestone, and Upper Limestone Shales. Professor Hull has given a classification of the Carboniferous Series throughout the country ('Quart. Journ. Geol. Soc.' 1877), based on the various stages which occurred during the deposition of the rocks. The author supports the principle of that classification, and is of opinion that the Lower Carboniferous rocks of Gloucestershire might be correlated with the same formation in the north of England. If this could be done it might be possible to adopt terms for the respective stages which would apply to the north and south of England, and thus avoid the complication of terms now in use.

The author then recited the stages which occur in the Carboniferous Limestone of Gloucestershire. Above the Old Red Conglomerate there appears a series of
1888.

sandy beds which are best developed in the Forest of Dean. These consist of micaceous green shales, and red purple and yellow sandstones. Some are calciferous and readily effervesce when treated with acid. No fossils have been found, but quartz pebbles occur in some of the beds.

The strata just referred to pass up into limestone and shales, the so-called Lower Limestone Shales. In the Forest of Dean the limestones are largely made up of the valves of Ostrocodæ, among which the following have been determined: *Kirkbya variabilis*, *K. plicata*, *Cytherella extuberata*, *Bythocypris sublunata*, and *Darwinula berniciana* (?). Among the other fossils which are numerous may be mentioned *Athyris Royssii*, *Rhynchonella pleurodon*, *Encrinites* and *Polyzoa*. Among the latter the following have been determined: *Rhabdomeson gracile*, Phill., and *Fenestella tuberculocarinata*, Ether. Junr. In the Lower Limestone Shales of the Bristol coalfield Ostracoda are not so plentiful, though in some beds the valves of these small Crustacea are numerous. *Rhynchonella pleurodon*, *Athyris Royssii*, *Productus*, *Spirifera* Crinoids and *Polyzoa* occur. At Clifton the Lower Shales are followed by a crinoidal limestone known as the Black Rock, which is about 490 feet thick, and is not represented in the Forest of Dean. The Black Rock series are followed by seventy feet of Dolomite, and then by about 100 feet of white oolitic limestone which the author regards as the true base of the Middle or Carboniferous Limestone. The author has grouped the Lower Limestone Shales with the Black Rock under the term Lower Limestones, and he considers the stage to occupy the horizon of the Tuedian and Calciferous series of the north of England and Scotland. As to the sandy beds which lie between the Old Red Conglomerate and Lower Limestone Shales the author regards them as the equivalent of the lower portion of the Transitional series of Phillips and the Calciferous of Scotland. The true upper limits of the Old Red Sandstone should be drawn at the Old Red Conglomerate.

As to the Middle Limestone there can be no doubt that it is the equivalent of the Carboniferous Limestone as generally understood, but the latter term the author thinks objectionable, and he would term the whole series Carboniferous Limestone. The Middle Limestone is largely made up of *Foraminifera* and *Calcisphæra*, but corals, polyzoa, crinoids, and shells occur, sometimes in quantity. In the Forest of Dean the Middle Limestone is extensively dolomitised.

Coming to the Upper Limestones; at Clifton it is difficult to draw the line at which the series should commence, as there is little alteration in the structure from that of the Middle Limestones. Corals are more numerous, coarse oolitic beds appear, and the beds become mixed with millstone grit. In the Forest of Dean the upper stage is well and clearly defined by two characteristic limestones known as the 'Crease' and 'Whitehead.' The former of these has become partially crystallised, but in some beds *Productus* is numerous, and also *Calcisphæra*.

The millstone grit is about 900 feet thick in the Bristol coalfield, and is a hard, slightly pink-coloured quartzite. In the Forest of Dean it is about 270 feet, and is a loose yellow red and mottled sandstone made up of well-rounded grains of quartz. The lowest beds are argillaceous and contain remains of *Lepidodendra*.

5. On the Tytherington and Thornbury Section. By the Rev. H. H. WINWOOD, F.G.S.

The author gave a short description of the section between Tytherington and Thornbury which members of the Association had an opportunity of visiting on the Saturday excursion. Beginning at Mr. Hardwicke's quarry, close to the Tytherington Station, the Carboniferous Limestone is seen rising sharply from the Gloucestershire Coal-field, followed by the whole series of beds of this formation, Upper, Middle, and Lower in descending order, until the Old Red Sandstone and Conglomerate appear at the Thornbury end. The chief points to be noticed in the Section are: (1) the 'Firestone' beds to be seen near the top of the quarry, dense siliceous beds marking the gradual coming in of the Millstone Grit. (2) The reversed fault bringing the fine-grained yellow beds of the Dolomitic Conglomerate similar to the

so-called Magnesian Limestone at Clevedon, against the Carboniferous Limestone, causing rolls and fractures for the space of some 500 feet, when the latter formation appears again, but now with the Dolomitic Conglomerate, everywhere resting horizontally on its upturned and denuded edges. (3) The cropping up of the 'Bryozoa' bed just before the last tunnel, giving a definite horizon for the correlation of this section with that at the Avon gorge. (4) The appearance at the base of the section of the Old Red Conglomerate with the coarse Dolomitic Conglomerate, containing pebbles of white quartz, Old Red Sandstone and Limestone, resting on its edges and with difficulty to be distinguished from the latter. (5) The reappearance at the end of the cutting of the same fine-grained yellow limestones divided by bands of shale and clay lying horizontally on the coarse Conglomerate beneath.

6. *The Northern Section of the Bristol Coal-field.*

By HANDEL COSSHAM, M.P., F.G.S.

After some general remarks on the character of the Bristol Coal-field, and its more complicated geological features, the author referred to the opinions of the principal geologists who have described the district, and recalled attention to his paper on a mistake in the geological maps of this Coal-field (read at the Bath meeting of the British Association in 1864).

He then drew attention to certain remarkable faults found in the Bristol Coal-field, with explanations of the same; and observed that they furnished illustrations of lateral pressure rather than of vertical movement.

He gave some account of the upheaval of the Mendip Hills, Broadfield Down, &c., subsequent to the formation of the Coal-field; alluding to the rent in the Palæozoic strata which forms the Severn valley, and to the severance of the Coal-fields of South Wales, Dean Forest and Bristol. A remarkable discovery was made by him, in 1884, of a great overthrust fault, the effect of which has been to double the known coal resources on the western side of the Bristol Coal-field. His observations threw some light on the complicated geological section of the Avon gorge, and on the future of the Bristol coal supply.

7. *Some Points of Interest in the Geology of Somerset.*

By W. A. E. USSHER, F.G.S.

[Communicated by permission of the Director-General of the Geological Survey.]

Three subjects were put forward as worthy of attention, and demanding a solution.

First. The position of the Carboniferous Limestone patches in the Coal-Measure area at Vobster and Luckington.

Secondly. The borderland between the Devonian and Culm Measures and the rocks of Old Red Sandstone and Carboniferous (proper) type.

Thirdly. The relations of the Lower Devonian beds in West Somerset.

In the first place, he suggested a thrust-fault through the Mendip axis carrying its upper portion northward so that the upward continuation of the Limestone on the north side of the Mendips should be shifted to the position indicated by the Vobster patches, the relations of these patches to the Coal Measures beneath and around being subsequently affected by step faults. This alternative hypothesis seemed to him more simple than Mr. H. B. Woodward's faulted anticlinal curves, and was merely put forward as a tentative hypothesis.

In the second place the author deprecated absolute correlations of divisions of Devonian and Carboniferous beds, whilst accepting the philosophical aspects of the general correlations of the late Professor Jukes and of Professor Hull. He considered that the area in which both types occurred side by side deserved primary attention. The relative position of the Cannington Park (Carboniferous) Limestone to the Middle Devonian rocks of the Quantocks and the Cannington and other inliers, supposed to be Middle Devonian, was given, as also the position of the

nearest Upper Devonian rocks and Culm Measures. From the strike of the Upper Devonian rocks he considered that they would be found under the Trias of the Vale of Taunton, and might trend northward under the Bridgewater Levels, till cut off by fault or unconformity bringing on the Carboniferous beds of normal type.

He believed a very careful comparison of the relations of the Belgian Lower Carboniferous and Upper Devonian rocks with the Culm Measures and Upper Devonian rocks of Devon and Somerset would throw much light on the question.

Lastly, brief allusion was made to the absence of the Lynton beds east of Luccot Hill, and to the possibility of their occurrence, as also of the presence of Foreland grits in the north of the Quantocks.

SATURDAY, SEPTEMBER 8.

The following Papers and Report were read:—

1. *Comparison of the principal Forms of Dinosauria of Europe and America.*
By Professor O. C. MARSH.

2. *The Evolution of the Mammalian Molar Teeth to and from the Tritubercular Type.*¹ By HENRY FAIRFIELD OSBORN.

Out of 82 species of mammals from the lowest Eocene of America (Puerco), all but four have *tritubercular* superior molars. From this type it is demonstrated that the molars of many of the Marsupialia of the Carnivora, Insectivora, Lemuroidea and Primates, Ungulata, &c., are derived, by the addition of cusps. To this type it is demonstrated that the molars of the Triassic and Jurassic mammalia lead. It is a central type.

The history of each of the cusps can be traced in all the mammals in which the molars have passed through the tritubercular stage. A nomenclature is therefore proposed as follows: the *protocone*, for the cusp which represents the primitive reptilian cone; the *para* and *metacones*, for the cusps on either side of this. These rotate inwards in the lower jaw and outwards in the upper jaw, to form the tritubercular type. In the lower molars a heel is next formed, the *hypoconid*, this leads to the formation of the intermediate cusps upon the upper molars, the *para* and *metaconules*. Finally the heel is formed upon the upper molars, the *hypocone*, completing the sextitubercular crown.

These stages of evolution are also named as follows: *protodont*, primitive reptilian crown stage; *triconodont* stage, with the large central and two lateral cones; *tritubercular* (Cope); *sexitubercular*, the parent ungulate type with six tubercles, and the *quadritubercular*. The lower molars pass more rapidly through the *tritubercular* to the *tubercular-sectorial* (Cope) and *quadritubercular* stages.

The development of the cusps is believed to be, in a measure, mechanical (Lamarck, Ryder, Cope): *a*. New cusps appear at points of vertical interference between upper and lower molars; *b*. Cusps take new shapes as a result of horizontal interference between upper and lower molars.

Not all mammalia are believed to have acquired this type. Those which have not are believed to have become extinct, this type having favoured the lines which acquired it. At any one period we find *progressive*, *conservative*, *central* and *persistent* types of molars, standing at various stages of the *tritubercular* evolution.

3. *On the Gigantic Size of some Extinct Tertiary Mammalia.*

By Professor A. GAUDRY.

The author drew attention to the very large size attained by some of the mammalia in later geological times, and instanced especially the skeleton of *Elephas*

¹ Published in *extenso* in the *American Naturalist*, December 1888.

primigenius in the Paris Museum, which is nearly five metres in height and which is exceeded by a specimen at St. Petersburg. The great *Dinotherium* of Pikerimi in Greece, found by Professor Gaudry himself, is of greater size still. The author expressed his satisfaction at finding that among British palæontologists there were now several who devoted themselves to the vertebrate as well as to invertebrate remains.

4. *Note on the Relation of the Percentage of Carbonic Acid in the Atmosphere to the Life and Growth of Plants.* By the Rev. A. IRVING, D.Sc., B.A., F.G.S.

The author refers to the discussion raised recently on this question in the pages of the 'Geological Magazine.' In order to test the hypothesis adopted by Professor Prestwich, three series of observations have been made during the past summer on plants exposed, under similar physical conditions, to atmospheres of different compositions. The evidence obtained all points in one direction, and goes to show that, with an increase of the percentage of carbonic acid up to about that of the free oxygen present, the vigour of plant life and growth is also increased, so long as the plants are freely supplied at their roots with water, as we have good reason to suppose was the case with the vascular cryptogams from which the carbonised materials of the coal-measures are for the most part derived. The author further considers the theory as throwing some light upon a certain stage of development of life upon the earth in later palæozoic time; the great development of plant growth in the carboniferous age having served as the means of storage of carbon in the earth's lithosphere, and thus purified the atmosphere so as to render it fit for the development of air-breathing forms of life in the Mesozoic Age.

5. *On the Occurrence of a Boulder of Granitoid Gneiss or Gneissoid Granite in the Halifax Hard-bed Coal.* By JAMES SPENCER. With a note by Professor T. G. BONNEY.

Many years ago, before the great importance of these boulders found in coal-beds was recognised, a fine specimen was found in the Hard-bed coal at Dam Head Pit, Shibdendale, near Halifax. It was a white hard rock streaked with small patches of a darker hue, almost as round as an orange, and about as large, and most highly polished. Having had my attention again called to these boulders by the discovery of quartzite boulders in the Black-bed coal at Leeds, two of them having been sent to me to prepare slices for examination under the microscope, I have been on the look-out for specimens from our local coal-beds, and was very fortunate to meet with one (in the spring of the present year 1888), which came from Shibden Head Pit, near Halifax. The boulder is of a greyish colour, four inches in length by about two and a half inches square. The angles have been worn off and the faces smoothed and polished, and afterwards transversely striated, the striæ being most probably due to slickensiding in the coal rather than to glaciation. It may be of use to note the exact locality and horizon in which the boulder was found. It came from the hard-bed coal at a depth of about 150 yards from the surface, and from under the north side of a hill called Barehead, in Shibdendale, near Halifax. The round boulder above mentioned came from the same bed, and from under the south side of the same hill, the two places being about half a mile apart. The geological horizon of the Hard-bed coal lies at about 60 to 70 yards above the rough rock, the uppermost member of the Millstone Grit series.

After preparing thin slices and examining them under the microscope, it was evident that the specimens presented a different structure from either of those from the Black-bed coal.

Professor T. G. Bonney, D.Sc., LL.D., F.R.S., &c., to whom a specimen had been sent, kindly describes it as follows:—'The boulder is one of unusual interest.

It is not a quartzite but a granitoid gneiss or gneissoid granite, probably derived from some mass of Pre-Cambrian age.

'The specimen practically consists of two minerals, quartz and felspar. The former occurs in grains of irregular outline, sometimes associated, and often joined, as it were sewn together, by microcrystalline quartz, which also occasionally extends into small patches. Numerous small enclosures give it a dusty look; many are empty cavities, some contain fluids.

'The felspar also occurs in grains of roundish to rather irregular outline, also often associated. It is much decomposed, but some is probably orthoclase, and microcline can be distinctly recognised. Parts occasionally are blackened by clustered granules. Without destroying the slide I cannot say whether these are iron oxide or some carbonaceous material which has infiltrated. As its presence has no important significance I have thought it needless to ascertain its precise nature, but believe it probably of secondary origin. Rather roundish grains of quartz are occasionally included in the felspar, as is common in old granitoid gneisses. I note a very little flaky viridite. It is possible that the gneissoid structure is due to mechanical deformation of a granite, but if so reconsolidation has been complete. The structure, in short, recalls a type of rock which is exceedingly common among gneissoid rocks which are universally admitted to be much older than any part of the Cambrian, and which is, so far as my experience goes, exceedingly rare, if not altogether wanting in any rock of Palæozoic or later date.'

6. *The Caverns of Luray.* By the Chevalier R. E. REYNOLDS.

These famous caverns are situated near the crest of a limestone hill of Silurian Limestone, near Luray Court House, in the valley of the South Shenandoah, Virginia, U.S.A. The valley is bounded on the east by the Blue Ridge Mountains, and on the west by the Massanutton range, the caverns lying equidistant from each. They were discovered in 1880, during which year the Smithsonian Institution sent out a scientific commission for the purpose of exploring and reporting on the same. The writer was a member of this commission.

The caverns—several distinct ones united by engineering operations—are similar to others found in limestone regions. They are mostly the result of erosion; one only—the Ramble, a plateau 500 feet long by 300 wide—resulting from displacement of the adjacent strata.

The predominating features are chambers, galleries, chasms, cascades, lakes, springs, and enormous columns.

The drapery is multiform in character, and many examples are highly ornate, a few being absolutely unique. The several styles or patterns will be named in the order of their growth.

Human remains have been found, but the character of their environment proves them to be of Indian origin. From the depth of the travertine which enclose them they appear to have been imprisoned for nearly a thousand years. The bones that are now visible consist of the right femur, the lower jaw, a rib, the segment of a clavicle, and a few teeth detached from the superior max. They appear to have belonged to a female of seventeen or eighteen years, the sex and age being determined by anatomical structure, ossification and dentition.

Columns.—Millions of them; some are 100 feet in circumference, and others 100 feet in height.

Stalactites.—They are very numerous and both single and compound, the latter forming 'sheet drapery' a hundred feet long and equally as wide.

Stalagmites.—Less numerous than the above, as much of the drip from the stalactites is converted into travertine.

Helictites.—Stalactites, usually small, which have ceased to enlarge vertically, their drip being diverted by polar influence and capillary attraction. The result is a horizontal, or obliquely perpendicular growth, in utter defiance of the 'Law of Newton.'

Travertine.—The result of a drip too excessive to permit the growth of stalag-

mites. The acidulous water spreads over the floor, rapid evaporation takes place, the calcite or carbonaceous residuum forming loose granular tufa or sinter, which slowly indurates in the form of compact travertine of variable depths.

Calc-Spar.—Found in abundance, tons of it having been removed by dynamite while levelling obstructions and battering doorways through intervening walls. The crystals are of the usual rhomboidal form.

Cucumbers.—Oblong convoluted objects found in the Coral Spring, and originating from nuclei.

Pearls.—Mechanical formation similar to the above, but differing in size and probably in material.

The collection of objects and photographs is sufficiently large to convey a fair idea of the several growths found in the caverns, and the characteristic appearance of the same *in situ*.

The writer's memoir on this subject embraces a vast amount of information on the early or incipient growth of stalactites, some of which is believed to be wholly original. He is also engaged in studying the ratio of stalagmitic growth in the Atlantic coast caverns. The result now obtained shows that the vertical growth of stalagmite is one inch in forty years. The growth of stalactites is nearly twice as fast, or one inch in twenty years. The glasses exhibited show the following:—

(1) The small glass, two years' deposit of carbonate under a medium drip.

(2) The goblet, three years' deposit under a constant, heavily-impregnated calcareous drip.

The caverns embrace a circuit of seven miles.

The specimens exhibited to the British Association for the Advancement of Science are the products of Luray and Weyer's caves. The polished sections are from Luray. They consist of stalagmites and stalactites—primary, compound, and drapery.

7. *Report on the rate of Erosion of the Sea Coasts of England and Wales.*
See Appendix, p. 802.

MONDAY, SEPTEMBER 10.

The following Papers and Reports were read:—

1. *The Volcanoes of the Two Sicilies.* By TEMPEST ANDERSON, M.D., B.Sc.

The author has recently visited the volcanoes of Naples, the Lipari Islands and Sicily, including Vesuvius, Stromboli, Vulcano, and Ætna, and taken photographs of their craters and some of their lava streams, and other most important parts, in order to obtain a record of their present condition which may be available for comparison in case of future eruptions. Some of these photographs were shown as projections on a screen by means of a lime-light lantern.

The summit of Vesuvius presents a sort of plain, consisting of the lava of 1872, in the north-eastern portion of which is the great crater excavated by the eruption of 1885, now nearly filled up by matters ejected since that time. A small secondary crater on the north-east part of its floor emits white vapour and occasional showers of red-hot pasty lava. An instantaneous photo of one of these explosions showed many of these up in the air.

Different lava streams exhibit different characteristics. The lava of 1872 was very quick flowing. Its surface is covered with angular masses of scoræ with sharp edges, and it is still devoid of vegetation.

On the other hand, that of 1858 was pasty and slow moving. Its surface presents rounded bosses with curious contortions, almost like great coils of ropes. It is now beginning to weather and support a few tufts of vegetation.

The island of Stromboli, one of the Lipari Islands, consists of a great volcanic

cone standing out of the deep water of the Mediterranean and rising about 3,000 feet above its surface. The north side has been partly breached, so that the active crater is now on the side of the mountain, about two-thirds of the way up. Explosions take place constantly from it at intervals of a few minutes, or occasionally longer. The ejected materials partly fall back into the crater and partly roll down the steep slope, or *schiera*, into the sea. The details of crater itself are constantly changing. A photo taken on May 17 showed two small cones on its floor, one of which constantly emitted clouds of vapour, while the other was that from which the explosions proceeded.

2. *Notes on the late Eruption in the island of Vulcano.* By TEMPEST ANDERSON, M.D., B.Sc., and H. J. JOHNSTON-LAVIS, M.D., F.G.S.

Both authors have visited the island of Vulcano, the former during the month of May of this year, and the latter just one year before. Both have photographed the principal points of interest; those of the latter were exhibited at the last meeting of the Association, and Dr. Anderson's are now shown before the meeting by aid of the lantern.

The island of Vulcano, so far as we can trace back its geological history, came into existence and was chiefly built up of a cone composed of doleritic lavas and related products. This large cone, traversed by radial dykes, some solid and some hollow, indicating the existence at one time of parasitic cones, was eventually destroyed by one or more explosive eruptions, and by truncating it very low, aided by subsequent denudation, reduced it to an irregular table-land. On this plain a fresh eruption took place, giving rise to small scoria cones and lava streams, some of which are basalts very rich in olivine.

This was followed by an eccentric explosive eruption, drilling a large crater out of the northern part and edge of this plain, and along this axis the present active cone of Vulcano was built up. This cone seems to have been formed at first of basic rocks, like that composing the main mass of the island, but subsequently highly acid products were erupted, composed of very acid pumices and lava streams of obsidian, very spherulitic in the interior. Lastly, still further north of this is the triple cone of Vulcanello, which, perched upon its own platform of lavas, constitutes an almost circular peninsula joined to the rest of the island by a narrow low neck of land. There is every reason to believe that Vulcanello has almost, if not entirely, been built up by eruptions of doleritic lavas and derivatives during the historic period, though at present only slight warm emanations of steam occur from a few cracks.

The main crater of Vulcano has also been in gentle solfataric activity from time to time, interrupted by paroxysmal eruptions. In its solfataric state the bottom and sides get more or less covered by sublimations of sulphur, boric acid, realgar, &c., whilst some distant rocks afford at present, and have from Roman times afforded, many varieties of the alums. For many years the sulphur and boric acid were collected for commercial purposes, but from the competition of Asia Minor and California the latter product has been neglected, and the English company who own the property have converted much of the island, described by Spallanzani a century ago as totally barren, into a rich vine, fig, and broom plantation, including more than 20,000 of vine plants.

The second of the authors described in 'Nature,' of this summer, the state in which he found the Lipari group of volcanoes in June 1887, and the first of the authors noticed no important difference three months since.

In 1886 a slight eruption cleared out the bottom of the crater of Vulcano, and since that time the crater has never 'entered into its former quiescent condition' to which the residents on the island are accustomed.

Mr. Narlian, whose villa is within a few hundred yards from the crater, very narrowly escaped with his and his children's lives. The following is the substance of his letter, and is, we think, quite worthy of being put on record:—

Lipari, August 30, 1888.

MY DEAR DR. JOHNSTON-LAVIS,—I have your kind note of 22nd inst. and will give you a short account of the strange doings of our old friend the crater of Vulcano.

On the 3rd inst. we had an outburst in the crater with stones, flames, thunder (regular lightnings). It was strong enough to throw stones of considerable size to the sides of the mountain. This lasted perhaps ten to fifteen minutes and then ended. After some time we began to have, at the interval of every twenty to thirty minutes, a great rush of thick smoke, and lasting some ten to twelve minutes at a time. We had often seen such eruptions during the twelve to thirteen years I have been on this island, and I hoped it would end like former eruptions. Towards evening, however, these rushes of smoke, steam, and ashes (which used to be projected into the air to about twice the height of the mountain) had completely ceased. As the night approached the leading fumarole (which was very active, giving off an offensive smell for months before the event) had begun to show a *clear high flame*, much paler than the flames produced by the burning of wood, and somewhat greenish or bluish. This phenomenon, together with the sudden stopping of the smoke, was evidently not a good omen. Consequently, I spent all the night dressed on a sofa in the drawing-room. Towards morning I was overpowered by sleep, and went to the little bedroom which looks towards the mountain, rested on the bed, and soon was sound asleep. Shortly afterwards I was awakened by a *tremendous din* which can hardly be described. As I jumped up from my bed I felt stones falling on the roof as hail—such cannonading going on—I understood what was the matter—ran to the opposite room, where I had made my children sleep that night. They were also up in consequence of an indescribable noise of thunder, rush of gases, flames, falling of huge boulders, rocks, &c. I took them to the drawing-room, but as soon as the door was opened a big stone *red hot* (all these stones are quite red with heat) fell through the roof, ceiling, and floor a few yards from us, smashing all, setting fire to everything. Now I took my children back to the bedroom, which looks on to the verandah, and tried to gain the terrace by that side. The house doors were shivering and shaking so that it was a difficult matter to open the doors. At last I succeeded, but before we were out in the verandah another stone fell at *our feet*, was smashed to fragments, and burned the feet and legs of my boys. Now we passed through the verandah, regained the house at the top of the stairs; here another stone fell very near us (none of these stones were less than 2 feet in diameter). This last stone (which is the fourth that struck the house including the one that fell on the ceiling of my bedroom while in bed) has nearly blocked our way out with the rubbish that it brought from the roof. We passed through over the heap of rubbish and were now out in the open to the north of the house. By this time (not many minutes after all) the whole place was lighted up, woods, grass, buildings, hedges—all was on fire; the huge boulders and stones were literally raining everywhere about us—what confusion! Natali, the faithful boy, had by this time come to the help of my little boys—we all began to run to Vulcanello and away from the dreadful thundering mountain. All the means of communication we possessed at Vulcano consisted in an old, half-broken 20-foot boat, and a lighter, both of which the men in their panic and mad despair had taken away with them, leaving us on the sands of Vulcanello. Towards noon, however, boats of rescue reached us from Lipari, and we thus ended one of the most eventful days of our life. How we escaped death I do not know.

On revisiting the spot I saw the whole plains below the mountain, to the distance of $1\frac{1}{2}$ mile, specially the neighbourhood of the house and the men's habitations, *literally* covered with boulders and rocks of all sizes, which had imbedded themselves in the ground to various depths. The most huge of them is near the well of the house, which is not less than 10 *yards* in diameter, and is some 10 to 11 feet deep in the ground. This is about $\frac{3}{4}$ of a mile from the crater. Another, of nearly equal dimensions, is on the shore near the Quarantana at the end of the bay of the Levante! Rocks of 1 yard in diameter are as plentiful as can be as far as the middle of Vulcanello, near the Punta Samossa! We have to thank God for going unhurt through this '*hail storm*'!

After this awful calamity, which has caused me so much loss, the crater has recommenced the rushes of steam, ashes, &c. This was a time of comparative diminution of activity, which had lasted for some days. Soon, however, it began the old game of throwing stones, boulders, ashes, &c., every two or three minutes, in all directions. No doubt many of these boulders are 10 to 15 yards across, and are projected as far as the sea, but often fall back into the crater itself. This state of things is continuing incessantly and uninterruptedly, causing further damage and frightening everybody.

During the last three or four days the noise of the thunder and eruption is so loud that from Lipari (at the distance of six miles) it would be impossible to distinguish it from a prolonged thunderstorm.

Yours truly,
A. E. NARLIAN.

In this letter we have a clear, unexaggerated account of the eruption that is well worthy, from its analogy, of being placed side by side with the renowned epistle of Pliny the younger to Tacitus. Until it is possible to examine the *primary or essential* ejectamenta the characters of the eruption seem to be, with slight doubt, of an intermediate stage between a paroxysmal and explosive eruption. The irregularity in the puffs of smoke and ejections of stones indicated that, as from time to time the crumbling sides of the crater blocked the vent, eruptive energy was for greater or less intervals suppressed until stored up energy or increased tension overcame the obstacle.

Another point of interest was the presence of flames, which are so rare in volcanoes, but have repeatedly been seen in this one. These are the result, no doubt, of the kindling of the sulphur deposited on the cooler parts around the fumaroles, which gets lighted by the hot stones and gases. The peculiar tint is in all probability due to the presence of boric acid (green) and sulphides of arsenic (grey blue). In fact a year ago the stones in the immediate neighbourhood of the great fumarole were covered by a boiling varnish of mixed realgar and sulphur, and when the latter author of this paper moved the stones, the outrush of steam bespattered those standing near with pearls of this compound. No doubt this presence of arsenic had increased of late and given rise to the special odour spoken of by Mr. Narlian.

One of us hopes soon to visit Vulcano and report more fully upon this late eruption.

3. *Report on the Volcanic Phenomena of Vesuvius and its neighbourhood.* See Reports, p. 320.

4. *On the Conservation of Heat in Volcanic Chimneys.* By H. J. JOHNSTON-LAVIS, M.D., F.G.S.

In various publications the author has endeavoured to enunciate the laws and explain the phenomena of the absorption of water by volcanic magmas and the liberation of the same. One group, however, of the phenomena were somewhat neglected, and it is to these that reference will now be made.

One who daily follows the phenomena of an active volcano such as Stromboli, Vesuvius, and others of the same type, cannot but be struck with the fact that the enormous evolution of watery and other vapours does not suffice to reduce the temperature of the magma to the point of solidification.

By carefully following the details of the varying activity of the above-mentioned volcanoes, which we will choose as our types, the matter becomes comprehensible. There is little doubt that all igneous magmas are originally in a vitreous condition, and that the passage from that state to a crystalline one must be accompanied by the evolution of an enormous amount of heat, just as occurs in the passage from the liquid state of water to the solid ice. Were the magma composed of a single chemical compound, we should expect that it would remain at a fixed temperature from the commencement of crystallisation to the complete

solidification as the result of that process. This would not be the case in the lava in a volcanic chimney, in which we should expect that the temperature would fall by steps, remaining fixed as long as any definite mineral species was crystallising, and would then drop to the crystallising temperature of the next species, again remaining for a certain time fixed. What these temperatures should be we do not know until the crystallising temperature of each rock-forming species is known. It must be remarked that the simple fusion point of any mineral is no indication of the temperature of the crystallising of a given mineral from a magma; for, in the former case we have to deal with a simple physical process, whereas in the latter it is often a chemical one. This is illustrated well in the case of orthoclase and augite, which both crystallise before leucite, which can only be explained by a chemical reaction taking place in the magma.

This process I take to be dependent upon a magma open to the atmosphere, by which the alkaline chlorides break up, the HCl being liberated and the free alkalis combining with the silica and alumina of the basic iron glass. Part of the iron separates as magnetite and part combines with the HCl and escapes in the vapour as chloride, always accompanied by some of the alkaline chlorides.

In fact, it seems an almost impossible task, the determining theoretically or even practically the temperature of solidification of a lava.

However, a clear comprehension of what has been said demonstrates how the supply of heat is kept up for a long time in the volcanic chimney, and the varying activity resulting therefrom. We have good reason to suppose that in our type of volcanoes there comes to the surface a uniform quantity of magma in a given time, although the extrusion may be more or less rhythmical, due to tidal and other agencies. Let us suppose that the magma has been so long simmering in the chimney that by volatilisation of steam, &c., it begins to become pasty. In that condition the escape of vapour from the lower part of the magma in the chimney cannot go on, and consequently the fall of temperature is arrested, although crystallisation may go on for some time, so that the temperature of the lava rises. Meanwhile more water is being dissolved or taken up by the magma, and, in consequence of this and the rise of temperature, the tension of the magma increases until it overcomes the resistance of the pasty magma choking the upper part of the chimney. There occurs a more or less strong paroxysmal eruption, in which, from the excess of water and the higher temperature there will result a tendency to the issue of the magma in a fragmentary condition, and this will approach more or less the scoriaceous or even pumiceous character. This is what is constantly occurring at Stromboli and even at Vesuvius, but in the latter it is much modified by the lateral oozing of lava, the effect of which I propose to treat of elsewhere.

In fine, we must conclude that the calorific capacity of the original vitreous magma must be very great, although its temperature may not be very high, and that its heat energy under favourable conditions may keep up the temperature for a long time. This would be the case in a volcanic chimney when solidification was taking place by crystallisation instead of cooling as a glass—a similar condition, in fact, to what we observe in the solidification of melted sulphur and other vitreous materials..

5. *Note on a Mass containing Metallic Iron found on Vesuvius.*

By H. J. JOHNSTON-LAVIS, M.D., F.G.S.

In the year 1882, during an excursion that I made on the slopes of Vesuvius to the N.W. of Camaldoli della Torre, a rusty-looking block about the size of a human head was met with loose on the surface. I was provided with a hammer sufficiently powerful to break up the usual size of ejected blocks, but on striking the mass in question, much to my astonishment, it persistently refused to break. A near examination revealed the fact that the spot where the blows had been delivered was malleable, and had been beaten out into scales. By a little manœuvring the block was eventually split up into various pieces.

The surface was rough and irregular, showing no patina of any kind, and was much rust-stained. The mass is principally composed of a dark grey vesicular

rock, with many scattered white glassy spots up to two millimetres in diameter. There are also many patches of buff, more spongy-looking rock passing into the surrounding grey mass. Scattered through the stony part are large masses of metallic iron, which in one section is 9 centimetres long by $1\frac{1}{2}$ in the broadest part. From eight to ten grammes of the metal were employed for a search after nickel and cobalt, but only gave faint traces of the former metal. A polished surface etched afforded no signs of Widemanstätten figures.

There being much doubt in my mind as to whether we had to deal with an artificial product or iron of volcanic or meteoric origin, I thought it safest to place it in the hands of some competent authority, and therefore sent one of the best fragments to Mons. Stanislas Meunier, who kindly promised to investigate the matter. From pressure of more important matters this investigation was delayed until last month, when my eminent friend published a short account in '*Le Naturaliste*,' April 15, 1888. His chemical researches agree with mine, as also do his microscopical, from which he describes the matrix as 'well-defined crystals enclosed in a vermiculated paste which encloses here and there a few opaque globules'; some of the crystals he considers to be oligoclase. There were also very regular rectangular and rather large hyalin crystals.

He very justly observes that if this mass is not an artificial product it is of considerable scientific interest. For over two years we had not corresponded; and the appearance of Mons. Meunier's paper rather took me by surprise, for had I known of my friend's intention of publishing his observations, I should have supplied him with further and more recent facts that have come to my knowledge, which to my mind render it very probable that we have to deal with an artificial product.

Against the supposition of this mass being of artificial origin we have its appearance and structure, which is not at all like what one usually sees amongst slags; secondly, there are no furnaces in the neighbourhood; thirdly, the piece is unique of its kind in the locality; and lastly, its mode and reason of transport were not obvious when I found it.

During the last two years I have met with, in the same neighbourhood, sandstone the surface of which is vitrified apparently by artificial heat, besides a mass of ordinary slag enclosing some fragments of half-baked limestone. In the next place I have been able to discover its mode of transport, which is worthy of description, as explaining the occurrence of many other rocks not belonging to Vesuvius, but common in the neighbourhood, such as Piperno, yellow tuff, Travertine, Nocerine tuff, Castellamare limestone, &c., the latter being exceedingly common, and all are more frequently met with in or near quarries of Vesuvian lava. The iron specimen also was not very far from some of the largest quarries on the mountain. In this neighbourhood all the carts for the transport of paving stones of Vesuvian lava have a frame consisting of two long poles balanced on two high wheels and prolonged into the shafts.

The carter, after having delivered his load, gets on his cart to ride back to the quarry, and to counterbalance his own weight on the front of the cart he places one or more stones at the tail about equal to his own weight. He naturally takes what is most handy, hence the great abundance of limestone blocks which are left in heaps along the sides of all the roads for repairing them when required. On the carter's arrival at or near the quarry these ballast stones are thrown away. The presence of these furnace products on the slopes of Vesuvius I account for by their having been brought from the ports of Torre del Greco or Torre Annunziata, where probably they had been thrown out from the ballast of some ship. At any rate, it seems justifiable to consider this iron of artificial origin until we have some more substantial grounds for considering such masses of natural origin.

In conclusion I wish to thank Mons. Stanislas Meunier for the trouble he has taken in the matter, and to express my regret for not having furnished him with further evidence, which I certainly should have done if I had known the matter had not dropped.

6. *Note on the Occurrence of Leucite at Etna.*

By H. J. JOHNSTON-LAVIS, M.D., F.G.S.

Some years since, whilst on a visit to Etna, my attention was drawn to some superficially placed tuffs of a chocolate to a coffee-brown colour. In these tuffs, near the Casa del Bosco, are observable included pieces of scoriaceous lava which to the naked eye are evidently leucitic; that mineral occurring in large well-formed crystals attaining to some millimetres in diameter, and brilliantly white as the result of fairly advanced kaolinisation. In consequence of this change the rock is excessively friable and, therefore, difficult to sectionise. A section of it, however, was exhibited at the meeting and also two photo-micrographs therefrom. In these it will be seen that kaolinisation has extended along the fracture planes of the leucites, whilst the beautifully formed pyroxene crystals are unaltered and the triclinic feldspars are fairly in a normal condition. The base is a microlitic network of feldspar and pyroxene, together with beautiful minute cubes and octahedra of magnetite, rendering the substance intervening between the crystals almost opaque even in thin sections. The pyroxene is often enveloped in a casing of leucite, as at Vesuvius, Roccamonfina, &c., confirming what I have asserted in other places, namely, that leucite is one of, if not the latest mineral to crystallise.

I regret that I have not the opportunity of investigating the question of the origin and age of this rock more completely, as on writing to my friend Professor O. Silvestri, inquiring if leucite had yet been encountered at Etna, I received a categorical answer in the negative, which, coming from such an authority, must be taken as conclusive as to the rarity of leucitic rocks being produced from Etna.

The discovery of this mineral at Etna is what one would have looked for, knowing as we do its wide distribution in nearly all the other late basic volcanoes of Italy.

7. *Note on some recent Investigations into the Condition of the Interior of the Earth.*¹ By Professor E. W. CLAYPOLE, B.A., D.Sc., F.G.S.

The difficulty of this great problem in geology was referred to in this paper as a reason for the slow progress made toward its complete solution, and the indirect nature of the evidence was also quoted as a source of uncertainty.

The chief element upon which reliance can be placed is the now seldom disputed datum that the earth must in all these inquiries be regarded as a heated body in cold space subject to laws of radiation as yet imperfectly understood.

Reference was then made to the recent investigations of Mr. C. Davison, Mr. T. M. Reade, Rev. A. Fisher, and Professor G. Darwin, claiming to prove that the following deductions from this datum have been established:—

- (a) That below 400 miles the cooling, and consequently the contraction, are imperceptible.
- (b) That the cooling, and consequently the contraction, reach their maximum at the depth of seventy-two miles.
- (c) That at the depth of five miles the contraction from cooling exactly equals the diminution of space due to the descent of the shell at that depth ensuing from the total vertical contraction of all the layers below it.

This layer at the depth of five miles has, therefore, been termed 'the layer of no strain,' being liable neither to extension nor compression, because the space is exactly sufficient for its diminished bulk.

The layer of 'no strain' is placed by one of the authors above named at the depth of five miles, and in a neutral zone between the bent and crushed strata above it and the compressed and horizontally extended strata below it. It is consequently impossible that any disturbance can occur in the layer of 'no strain.'

Yet in some parts of the earth, and notoriously in the Appalachian region of North America, strata have been forced up from a depth greatly exceeding this limit.

¹ Published in the *American Geologist* (Minneapolis, Minnesota) for June and July 1888.

Beds are now exposed which, at the time of their folding, lay fully eight miles below the surface, and must, therefore, have been far below this neutral zone, which was then (at the end of the Palæozoic Age) less than five miles deep.

Similar facts might be adduced from other parts of the world, and it is therefore difficult to avoid the conclusion that the layer in question has been placed too near the surface, though of the actual existence of such a zone, after a careful study of these investigations, scarcely a doubt can be entertained.

It should further be urged, as another difficulty lying in the way of the implicit reception of the numerical conclusions of the mathematicians, that if the layer of 'no strain' lie at the depth stated, all seismic foci must be situated at less depth. Many of them doubtless are so, but that of the great Neapolitan earthquake of 1857 was placed by Mr. Mallett at the depth of seven miles, and that of the Charleston earthquake of 1886 at the depth of twelve miles. Without pledging ourselves to exactness in these figures, it is somewhat difficult to reconcile them with those of the mathematician.

Little doubt can be entertained that an actual and existing state of things has been revealed by the mathematicians, needing, however, the joint action of themselves and the physicists in order to adjust its details.

8. *On the Causes of Volcanic Action.* By J. LOGAN LOBLEY, F.G.S.

After citing recent opinion as to the absence of an adequate explanation of the causes of volcanic action, the author showed that the accumulation of knowledge of the controlling facts of volcanic phenomena and the amount of attention which had been given to the question placed the subject on firmer grounds, and made the finding of a satisfactory solution of the problem now more probable.

The difficulty of the question lay in the great number of facts and the apparent conflict of many of them.

It was, in the first place, necessary that the leading and controlling facts should be recognised and kept in view. With this object a compendium or concise statement of forty-five such facts was given, followed by a brief review of the various theories that had been advanced from Lemery's in 1700 to Prestwich's in 1886, with in each case numerical references to the facts in the compendium which were in the author's opinion at variance with the respective hypotheses.

The author's own conclusions were then submitted, which are briefly as follows:—

A. That the primary cause of the formation of lava is the internal heat of the globe inducing chemical action in subterranean regions where the materials and conditions are both favourable.

That since the fusion-point of temperature of solids is raised by extreme pressure, conditions for chemical action may be changed from unfavourable to favourable by the removal or relief of vertical pressure by lateral or tangential pressure.

That certain substances are fusible at low or moderate temperatures, and that thus at very moderate depths chemical action may be locally commenced that will extend until sufficient heat is produced to effect rock-fusion.

B. That the cause of the ejection of lava from its source, and its rise in the volcanic tube is the increase of bulk consequent upon the change from the solid to the fluid state, aided by the formation of potentially gaseous compounds by chemical reactions among the original materials of the magma.

That the ascent of the lava in the volcanic tube may be affected by the weight of the atmosphere and by lunar attractive influence, and that therefore a volcanic vent is a thermometer, and, secondarily, a barometer and heliometer¹ combined.

C. That the explosive effects of volcanic eruptions are altogether secondary, and are due to the access of sea and land water, by percolation through cool rocks, to fissures up which lava is ascending.

That this water, when converted into steam, opens, by its expansive power,

¹ From ἑλκῦσις — εως = attraction.

rents that admit large flows of sea-water to the lava, occasioning the formation of vents and the greater explosive phenomena of eruptions.

The formation of the actual surface volcano and the determination of its position is therefore due to the sea, near which volcanoes are almost always situated.

Emissions of lava without explosive effects are from volcanic tubes to which large flows of water have not obtained admittance, and, on the other hand, purely explosive eruptions, without lava-flows, are caused by water reaching lava which fails to rise to the surface of the earth.

The various forms of volcanoes the author considered could be explained by these views, which opposed:—

1. An infra-crust common central source of lava.
2. The passage of lava through 30 miles of rocks, and consequently through any greater thickness.
3. The ejection of lava from its source by vertical pressure.
4. The ejection of lava from its source by super-heated steam or 'potential steam' force.
5. The passage of water through highly-heated rocks, either by fissures or by capillary transmission.
6. The accumulation or the presence of water at volcanic foci.
7. A primogeneal 'water substance.'
8. The importance of land surface water.

The author had given much thought during many years to volcanology, and had made personal observations of volcanic activity; and whether his views were approved or not he would be glad if they elicited facts and opinions that would further a solution of the problem. He thought a discussion on the subject would not be inappropriate at the city of Bath, famous as it was for thermal waters deriving their heat from what might be termed, according to his views, a volcanic focus, but in this case one from which only benefit to mankind was received.

9. *Eighth Report on the Earthquake and Volcanic Phenomena of Japan.*

See Reports, p. 422.

10. *On the recent Volcanic Structure of the Azorean Archipelago.*

By OSBERT H. HOWARTH.

The object of the author's notes upon the relation of the Azorean group to the other islands of the West Atlantic is to indicate a line of inquiry by which some approximation may be made to the intervals separating the great eruptive changes; and determining any modifications in the type of flora during that important succession of volcanic products which has been evolved since the Upper Miocene period assigned to the islands generally. A field for such inquiry seems to be offered by the present phase of action in the Furnas district, in the eastern centre of St. Michael's, where existing activity is associated with some of the oldest formations in the series. The author has traced in that valley a series of beds of vegetable origin dating back from the most recent changes, immediately connected with the present boiling-spring area, to a period antecedent to the formation of the Furnas Valley itself. The intermediate intervals of repose are now represented by peaty beds and subaqueous vegetable deposits, interstratified with the successive lava streams, tuffs, and pumice-beds of various dates, within and prior to the historical period. From the more recent of these, buried trunks and branches have been obtained which represent the intervals of recent eruptions; while in one of the older tuffs, underlying nearly the whole series at that portion of the islands, a tree (probably an *Erica*) has been found, presumably *in situ*, and offering possibilities of a subjacent soil for examination, which would be contemporaneous with the earliest vegetation of the island.

11. *Report of the Earth Tremor Committee.*—See Reports, p. 522.

SUB-SECTION C.

1. *The Watcombe Terra-Cotta Clay.* By W. A. E. USSHER, F.G.S.

[Communicated by permission of the Director-General of the Geological Survey.]

The Lower Trias Conglomerates at Watcombe rest upon about 20 feet of sandstones made up of comminuted slate; these are succeeded by red marly and shaly clay, cut off by fault at the south boundary of Watcombe Combe, but reappearing on the south side of the intervening faulted mass of conglomerate, in Petitor Combe, where the beds of marl and clay are apparently at a lower horizon than those of Watcombe, and they are interstratified with sandstones made up of comminuted slate. They rest on broken limestone, through which the red mud has permeated. The junction-beds are in places local masses of breccia.

The series above described is visible nowhere else on the coast, but has been traced inland by the author to Kingskerswell and Torre. Its character changes in this westerly extension, the sandstones often assuming the aspect of a fine breccia, and the clay becoming an indurated mudstone, brecciated in places. About 40 feet of these beds are exposed in a large pit near the Torquay Cemetery, where they are faulted against Devonian slates. Beds on this horizon, apparently, consisting of clay and loam with gravelly detritus dispersed throughout, occupy the slopes of the Dacombe Valley, near Kingskerswell on the east. In the Wellington Co.'s (Thomas) pits a small mass of porphyrite occurs in the sands and loams which there constitute the upper part of this series. Towards Torre Station the Watcombe clays pass under breccia and conglomerate; red marl and shaly clay occur in the railway cutting.

To the north of Kingskerswell the Watcombe clays do not appear to have extended far, as the conglomerate and breccia of the overlying beds rest on the Devonian rocks bordering the estuary of the Teign.

To the south and west of Torre and in the Paignton area no lithological equivalent to the Watcombe clays has been observed. But it is quite possible that contemporaneous deposition took place in these districts; the components of the Lower Trias exhibiting such frequent local variation that no great faith can be placed in the maintenance of lithological distinction on definite horizons.

The Watcombe clays, however, may be the oldest Triassic rock in South Devon, and may have attained a much greater development to the eastward of the present coast, although restricted within narrow limits in their westerly extension.

The author concluded by adhering to the classification he had propounded for the Triassic rocks of the south-western counties, and saw no reason to alter the position therein assigned to the Watcombe clay.¹

2. *Second Report on the 'Manure' Gravels of Wexford.*

See Reports, p. 133.

3. *Beds exposed in the Southampton New Dock Excavation.*

By T. W. SHORE, F.G.S., F.C.S.

The beds described in this paper have been exposed during the progress of an excavation of eighteen acres for the purposes of a deep-water dock at Southampton. The site of the excavation is at the junction of the tidal rivers Itchen and Test in the Southampton water, the area excavated having previously been covered with tidal water to a depth varying from 12 to 17 feet. The excavation has brought to light the succession of beds to a depth varying from 36 to 42 feet below the surface of the alluvium over this area. From 5 to 17 feet of tidal alluvium lay at

¹ In a paper by Mr. Appleton 'On Economic Geology of Devon' (*Trans. Dev. Assoc. for 1875*, p. 241), an analysis of the Watcombe clay, by Dr. Percy, is given.

the top, which contained within it and on its surface abundance of the marine shells *Cardium edule*, *Buccinum undatum*, *Purpura lapillus*, *Murex arenaceus*, *Tellina Balthica*, *Tapes decussata*, *Litorina litorea*, *Trochus cinerareus*, *Hydrobia ulva*, *Lucina borealis*, species of *Scrobicularia*, *Rissoa*, *Nassa*, *Mytilus*, and others.

Beneath the tidal alluvium over the greater part of the area, peat was found in thickness varying from 2 to 14 feet, being thickest towards the Itchen side of the excavation, and as a rule thinnest on the Test side. At the Test side of the excavation, and dipping sharply towards the Itchen under the thick peat on this side—at one time a dark line of peat parallel with the present course of the Itchen, and on a level with the gravel terrace, could be seen stretching out into the estuary towards the junction of the river channels. The colouring matter of a green sand found in the gravel just below the alluvium has been examined and analysed by Mr. J. Brierly, public analyst for Southampton.

The Bracklesham beds lying beneath the gravel were found to be largely composed of green sand or green sandy clay coloured with glauconite, below which a dark clay was met with. On the Itchen side of the excavation, where the gravel is comparatively thin and occurs beneath very thick peat, the Bracklesham clay just below the gravel was found to be dark-coloured. Some remarkably large sand pipes, very fine specimens of *Venericardia planicosta*, *Turritella sulcifera*, and large pieces of pyritised wood, have been found in the Bracklesham beds, the compact sandy clays of which showed some well-marked joint planes discoloured by infiltration and oxidation. About fifty species of Bracklesham mollusca have up to the present time been found.

The loss of cattle and the native ponies of the New Forest during wet seasons in the deep New Forest bogs at the present time, appears to explain the occurrence of animal remains in the peat.

Some Neolithic remains were found in the peat, consisting of dark-coloured flint flakes, such flint chips being met with on one occasion all lying within a few feet of each other, the site probably marking the spot where a Neolithic worker had fashioned his implement. A very fine specimen of a round hammer-stone was also found in the peat about twenty feet below the surface of the alluvium, the hammer being $3\frac{1}{4}$ inches in diameter, and having a circular hole $1\frac{3}{4}$ inches in diameter at the sides, and $\frac{7}{8}$ inch in diameter in the middle. It weighs 1 lb. 9 oz., and is made of fine greywether sandstone, and is one of the finest of its kind recorded as having been found in England.

The gravel beneath the peat was found partly in ridges with thick peat between the ridges, but this character did not extend far. A great part of the area after the removal of the upper beds presented the appearance of a gravel terrace, the gravel lying highest on the north-western part of the excavation; the alluvium was found to rest on gravel, peat being absent.

The peat was found to contain within it extensive beds or pockets of shell marl or fresh-water tufa containing abundance of shells of land and fresh-water species—*Limnea peregra*, *Limnea stagnalis*, *Limnea palustris*, several species of *Helix* and *Planorbis*, *Pisidium amnicum*, *Bithinia tentaculata*, *Hydrobia ventrosa*, and *Valvata piscinalis*. The tufa much resembled large patches of a similar kind, which occur just below the surface of the alluvial meadow land in both the river valleys from ten to twenty miles higher up the streams.

The peat contained much bog-oak, with large trunks *in situ*, and remains of beech, hazel, birch, fir, and apparently the bog myrtle, heaths, bracken-fern, sedge, and bulrush.

The animal remains found in this peat comprised the horn cores and parts of the skull of *Bos primigenius*—one a very fine specimen, described by the author of the paper in the 'Geological Magazine' for November 1887—many bones of the *Bos*, and many horns and bones of *Cervus elephas*. Some bones of a small variety of horse were previously found in this peat, from which was also obtained the tusk of a boar and some bones of the hare.

4. *Fossil Arctic Plants from the Lacustrine Deposit at Hoxne, in Suffolk.*
By CLEMENT REID, F.G.S., and H. N. RIDLEY, M.A., F.L.S.

Near the village of Hoxne, close to the northern border of Suffolk, and about five miles east of Diss, lies the well-known lacustrine deposit from which Palæolithic implements were obtained more than ninety years ago. This deposit has been so well described that it may seem presumptuous to imagine that there is still anything new to say about it. But it so happens that every observer up till now has studied the deposit either from an archæological or from a geological point of view. No one has paid special attention to the character of the associated plants, or to the climatic conditions which these plants indicate.

This deposit was described in 1797 by John Frere, and afterwards, in 1860, by Professor Prestwich, who gave numerous details and showed that the lacustrine deposit rests in a hollow in the Boulder Clay.

The following is an abstract of the section given by Professor Prestwich :—

SECTION IN SOUTH-WEST CORNER OF HOXNE BRICKFIELD.

	Feet
a. Surface soil	1 to 2
b. Brown and greyish clay, not calcareous. Two flint implements. Bones of <i>Bos</i>	10 to 12
c. Yellow sub-angular flint gravel. <i>Elephas</i>	$\frac{1}{2}$ to 1
d. Bluish and grey calcareous clay, in places very peaty. Wood and vegetable remains. Land and freshwater shells. Deer, horse, elephant	3 to 4
e. Gravel like c, but smaller	1 to 2
f. Calcareous grey clay, more or less peaty, with freshwater shells (bored to 17 feet, but no bottom was reached)	17

The mollusca, to which the authors added two or three unrecorded species, are all forms having a wide range. The plants obtained from bed *d* throw more light on the climatic conditions. They include twenty-seven flowering plants, one *Chara*, and ten mosses. The specimens are chiefly seeds and fruits, with leaves of willow and birch and wood of yew. The mosses are all fragments of the stem with leaves attached. The list of species shows that the flora was an Arctic one corresponding in many features to that of Iceland. The presence of *Betula nana*, *Salix polaris* and *S. myrsinites* is sufficient to show this. The latter Sallow has not been hitherto recorded as fossil, but its leaves are the bilberry-like foliage mentioned by Professor Prestwich. *Salix polaris* is now only known from very high arctic latitudes, but it is well known as a fossil in glacial and post-glacial deposits. The mosses which Mr. Mitten has identified for us have also an arctic or alpine facies. *Acroceratium sarmentosum* is now an inhabitant of the higher mountains of Killarney and Scotland, as well as the arctic regions. The Cornel is represented by a single large seed, differing somewhat from the common form and perhaps a variety.

The larger part of the plants represented are aquatic or marsh plants, and nearly all are plants still occurring in high latitudes at the present day; but the Yew, Bur-reed, Cornel, and *Potamogeton trichoides* are absent from the arctic regions.

The flora thus suggests the approach of a warmer climate following a cold one, so that the arctic flora had not entirely gone by the time that the more temperate one had begun to come.

5. *Report on an ancient Sea Beach near Bridlington Quay.*
See Reports, p. 328.

6. *On the Origin of Oolitic Texture in Limestone Rocks.*
By Professor H. G. SEELEY, F.R.S.

The author believed that oolitic texture might originate in many ways. It was stated to be found in limestones and iron ores of Silurian, Devonian, and Carboniferous age, but to be most characteristic of the inferior and great oolite;

coralline oolite, and Portland oolite. Experiment has shown that a pseudomorph of carbonate of lime may be obtained when carbonate of soda is acted upon by chloride of lime; and he thought that many oolitic grains were pseudomorphs. In the magnesian limestone grains of dolomite present all the characters of oolite. In the carboniferous limestone it is common for large foraminifera to be the nuclei of oolitic grains so as almost to justify the view of Dr. W. B. Carpenter that oolites are foraminiferal limestones where the foraminifera are coated with calcite. In the secondary oolites nuclei are less frequent, and often include several grains of sand. It is difficult to account for a pellet of sand acting as a nucleus, but the author believed the interpretation of Dr. Sorby to be satisfactory with a single nucleus. The author attributed the small size of the grains to the small transporting power of the current which is assumed to have formed them by rolling.

Almost all limestones are of organic origin, and the author drew attention to the close resemblance of the internodal grains of the nullipores to grains of oolite as furnishing a further explanation of oolitic texture. These grains show a concentric structure as well as a radiated tubular structure, which would favour the recrystallisation such as commonly occurs.

TUESDAY, SEPTEMBER 11.

The following Papers and Reports were read:—

1. *Notes of some Researches on the Fossil Fishes of Chiavòn, Vicentino (Stratum of Sotzka, Lower Miocene).* By Professor FRANCESCO BASSANI.

These fossiliferous Marls were first discovered by Baron Zigno in 1852, who referred them to the Lower Miocene, since which time Heckel, Heer, Molon, Bayan, and Messrs. Liroy, Suess, Sauvage, Hébert, Munier-Chalmas, Stur, Friedrich, and Staub have studied their fauna and flora.

The abundant materials here investigated were derived from many public and private museums, and represent plants and animals, amongst which are a few crustaceans badly preserved, very few insects, many beautiful fish, two bones of birds, and some amphibia.

The plants were described by Massalongo and Roberto di Visiani, the insects by Omboni and Heckel, Kner, and Messrs. Steindachner and de Zigno have occupied themselves with the Ichthyolites. At this epoch the fish-fauna of Chiavòn was represented by seventeen species, of which only six were figured, as follows:—

| 8. <i>Engraulis brevipinnis</i> , Heck. (not fig.). | 17. ? <i>Mene</i> (not fig., not descr.). |
| 9. <i>Chanos brevis</i> (Heck.) Kner St. (fig.) (<i>Albula brevis</i> , Heck.). | |

My researches have augmented in a notable manner the number of species, which now amounts to fifty-eight, as may be seen from the following table. This shows, at the same time, their tropical and marine characters.

EUICHTHYES.

PALAEICHTHYES.

CHONDROPTERYGII.

Fam. Galacidae.

Gen. GALEOCERDO, Müller et Henle.

1. *Galeocerdo priscus* (Heck.), Zigno.
(*Galeodes priscus*, Heck.).

Gen. MYLIOBATES, Duméril.

2. *Myliobates Clavonis*, Zigno.
3. *Myliobates leptacanthus*, id.

TELEOSTEI.

ARTHROPTERI.

PHYSOSTOMI.

Fam. Scopelidae.

Gen. SCOPELOIDES, Wettstein.

4. *Scopeloides Nicolisi*, n. sp.

Fam. Clupeidae.

Gen. CLUPEA, Linneo.

5. *Clupea breviceps*, Heck.
6. *Clupea latissima*, id.
(*Alausa latissima*, id.).
7. *Clupea gracillima*, Heck.
(*Meletta gracillima*, id.).
8. *Clupea sagorensis*, Steind.
9. *Clupea sagorensis*, St. var. *arcuata*
Kner (*Clupea arcuata*, Kner).
10. *Clupea* cfr. *lanceolata*, Meyer.
11. *Clupea inflata*, Vukot.
12. *Clupea Ombonii*, n. sp.
13. *Clupea Grandonii*, n. sp.
14. *Clupea*, sp.

Gen. ENGRAULIS, Cuvier.

15. *Engraulis longipinnis*, Heck.
16. *Engraulis brevipennis*, id.

Gen. CHANOS, Cuvier.

17. *Chanos Zignoi* (Heck.) Kner et St.
(*Albula Zignoi*, Heck.—*Alb. lata*, id.).
18. *Chanos brevis* (Heck.) Kner et St.
(*Albula brevis*, Heck.).

ANARTHROPTERI.

HAPLOPTERI.

Fam. Gobiidae.

Gen. GOBIUS, Lacép.

19. *Gobius*, sp.

ACANTHOPTERI.

PHARYNGOGNATHI.

Fam. Labridae.

Gen. LABRUS, Artedi.

20. *Labrus Agassizi*, Heckel.

ACANTHOPTERIS. STR.

Fam. Cottidae.

Gen. *Lepidocottus*, Sauvage.

21. *Lepidocottus aries* (Ag.), Sauv.
(*Cottus aries*, Ag.).
22. *Lepidocottus elongatus*, n. sp.

Fam. Percidae.

Gen. LATES, Cuvier.

23. *Lates macropterus*, n. sp.

Gen. LABRAX, Cuvier.

24. *Labrax* cfr. *Neumayri*, Kramb.

Gen. SMERDIS, Agass.

25. *Smerdis analis*, Heck.
26. *Smerdis aduncus*, id.
27. *Smerdis minutus*, Ag.
28. *Smerdis Taxramellii*, n. sp.

Gen. GERRES, Cuvier.

29. *Gerres Massalongi*, Heck.

Gen. APOGON, Lacépède.

30. *Apogon Krambergeri*, n. sp.

Gen. ANTHIAS, Cuv.

31. *Anthias* cfr. *stiriacus* (Rolle) Bass.
(*Serranus? stiriacus*, Rolle).

Gen. SERRANUS, Cuv.

32. *Serranus rudis*, n. sp.
33. *Serranus*, sp.

Fam. Sparidae.

Gen. SPARNODUS, Ag.

34. *Sparnodus Moloni*, n. sp.
35. *Sparnodus intermedius*, n. sp.
36. *Sparnodus*, sp.

Gen. PAGRUS, Cuv.

37. *Pagrus Meneghinii*, n. sp.

Gen. CHRYSOPHRYS, Cuv.

38. *Chrysophrys Zignoi*, n. sp.
39. *Chrysophrys Scacchii*, n. sp.

Fam. Scomberidae.

Gen. ORCYNUS, Cuv.

40. *Orcynus medius*, n. sp.

Gen. SCOMBER, Cuv.

41. *Scomber* cfr. *antiquus*, Heck.

Gen. CYBIUM, Cuv.

42. *Cybium*, sp.

Gen. MENE, Lacép.

43. *Mene oblonga* (Ag.), Zigno, var. *pusilla*,
n. var.

Fam. Carangidae.

Gen. CARANX, Cuv.

44. *Caranx ovalis*, Heckel.
45. *Caranx rigidicaudus*, id.

Gen. LICHIA, Cuv.

46. *Lichia Stoppanii*, n. sp.
47. *Lichia lata*, n. sp.

Gen. AMPHISTIUM, Ag.

48. *Amphistium dubium*, n. sp.

Fam. Squamipennidae.

Gen. SCATOPHAGUS, Cuv.

49. *Scatophagus Capellinii*, n. sp.
50. *Scatophagus affinis*, n. sp.

Gen. HOLACANTHUS, Cuv.

51. *Holacanthus Piovenorum*, n. sp.

Gen. PYGAEUS, Ag.

52. *Pygaeus aff. Coleanus*, Ag.
53. *Pygaeus cfr. oblongus*, id.
54. *Pygaeus Zignoi*, n. sp.

Fam. Sciaenidae.

Gen. ODONTEUS, Ag.

55. *Odonteus cfr. sparoides*, Ag.

Fam. Sphyraenidae.

Gen. SPHYRAENA, Blainv.

56. *Sphyraena cfr. bolcensis*, Ag.
57. *Sphyraena intermedia*, n. sp.

Fam. Palaeorhynchidae.

Gen. PALAEORHYNCHUS, Bl.

58. *Palaeorhynchus cfr. glaronensis*, Bl.
emend., Wettst.

An examination of this list shows that the Chiavòn fauna includes no Ganoids, and is constituted of Chondropterygeans and Teleosteans. The first are represented by two families, with two genera and three species. The second comprehend the Arthropteri and the Anarthropteri; the former with two families, four genera, and fifteen species; the latter with eleven families, twenty-six genera, and forty species. The whole are therefore comprehended in fifty-eight species, distributed in thirty-two genera and fifteen families.

Comparing the fish-fauna of Chiavòn with twenty-one other analogous deposits of Europe, I have come to the conclusion that they are in age Aquitanian, or belong, like the strata of Sotzka, to the base of the Lower Miocene.

(The original memoir, and the figures which accompany it, will be published in the 'Atti della R. Accad. delle Scienze Fisiche e Matematiche di Napoli.')

2. *Sixth Report on the Fossil Phyllopoda of the Palaeozoic Rocks.*
See Reports, p. 173.

3. *Report of the Committee for investigating the Flora of the Carboniferous Rocks of Lancashire and West Yorkshire.*—See Reports, p. 150.

4. *On an Ichthyosaurus from Mombasa, East Africa, with Observations on the Vertebral Characters of the Genus.* By Professor H. G. SEELEY, F.R.S.

The author described two cervical vertebrae of an Ichthyosaurus from low-lying country nine miles N.W. of Mombasa, brought to this country by Mr. New, a missionary, and submitted to the author by Mr. Harris, F.G.S. The specimens are from the cervical region, and differ in no way from such as occur in the English Secondary clays. They are probably of Lower Secondary age. The vertical height is 73 millimetres, the transverse width is 77 mm., and the antero-posterior length is 34 mm. The author finds that the ratio of height to width and of height to length, is a good means of distinguishing vertebrae in different species, and that, when it is determined for each region of the body, it forms and furnishes a valuable datum for defining a species on vertebral characters. The

author specified the vertebral characters which should be observed, as size, number in the several regions, proportions of centrum in each region, proportions of vertebræ to limb bones and to the skull.

5. *A Comparison of the Cretaceous Fish-fauna of Mount Lebanon with that of the English Chalk.* By A. SMITH WOODWARD, F.G.S., F.Z.S.

No detailed comparison having hitherto been instituted between the Cretaceous fish-fauna of Mount Lebanon and that of the English chalk, which belongs to a well-determined horizon, the author has undertaken a general survey of the genera, with the result that the two faunas are proved to have more forms in common than hitherto supposed. The Selachian fishes are scarcely comparable, *Notidanus* and *Squatina* being the only genera as yet recognised in the two formations, although the English teeth named *Lamna rhapsiodon* seem to belong to the shark named *Rhynchognathus*; on the whole, those of Mount Lebanon exhibit the most modern facies, all traces of Hybodont Sharks and of *Ptychodus* being wanting. Chimæroids are unknown at Mount Lebanon, but abundantly met with in the English Chalk. Among Ganoids there are representatives of the Pycnodonts both in the Lebanon (*Palæobalistum*, *Coccodus*, *Xenopholis*) and in England (*Cælodus*), but no identical genera can yet be recognised. Rhombic-scaled Ganoids are rare in the English Chalk (*Lophiostomus*, *Neorhombolepis*), and unknown in Mount Lebanon; traces of Acipenseroids also occur in the former, but have not been discovered in the latter; and at least one Crossopterygian genus occurs plentifully in England (*Macropoma*), while no uncertain remains have been detected in the Syrian beds. *Belonostomus*, however, is common to the two formations, one species having been described from Mount Lebanon under the name of *Rhinellus laniatus*.

Of Physostomous Teleosteans, the great early families represented in the Chalk of England and the Upper Cretaceous of North America by *Portheus*, *Ichthyodectes*, *Protosphyæna* and *Pachyrhizodus*, are quite unknown in the deposits of Mount Lebanon; but in the latter locality *Enchodus* is abundant, having been described under the synonym of *Eurygnathus*, and this is accompanied by a closely-allied genus, *Eurypholis*, only differing in the possession of a few dermal scutes. The English *Pomognathus* may also be regarded as represented at Mount Lebanon, for the so-called *Phylactcephalus* merely differs in the presence of extremely delicate minute scales, which would not be preserved in a matrix of the nature of the Chalk; and *Aspidopleurus* (Mount Lebanon) possesses scutes indistinguishable from the detached examples long known in the English Chalk under the name of *Prionolepis*. *Dercetis*, also, is met with abundantly in the Syrian beds, being described under the synonym of *Leptotrachelus*. Among Elopine Clupeoids, some undescribed forms occur in the English Chalk, and one from Mount Lebanon has been erroneously assigned to the genus *Clupea* ('*C. Lewisii*'); and the supposed Salmonoid, *Osmeroides*, is common to the two formations, though inferior in size at the last-named locality. In the Syrian deposits, however, there are many more specialised Physostomi, such as *Cheirothrix*, *Spaniodon*, *Opistopteryx*, *Rhinellus*, *Scombroclupea*, *Diplomystus*, and *Clupea*, of which no traces appear to be discoverable in collections of English Chalk fossils. Among Physoclystous Teleosteans but few genera are common to the two formations under comparison. *Hoplopteryx*, with perhaps *Beryx*, represents the Berycidæ in both localities; but only a single imperfect specimen from the English Chalk can yet be assigned to any higher type, namely, *Platax* (?) *nuchalis*. At Mount Lebanon more specialised Physoclysti are numerous, as *Platax*, *Imogaster*, and *Pycnosterinx*; although to the latter have been erroneously assigned certain extraneous forms, including at least one well-marked Berycid, the so-called *Pycnosterinx Lewisii*.

The conclusion is thus arrived at, that in those respects in which the Lebanon fish-fauna differs from that of the English Chalk, it exhibits greater specialisation. Considered alone, therefore, it is distinctly of a more modern type than the latter, although the beds in which it occurs are regarded, from other evidence, as being of Turonian age.

6. *On Bucklandium diluvii, König, a Siluroid Fish from the London Clay of Sheppey.* By A. SMITH WOODWARD, F.G.S., F.Z.S.

In his well-known 'Icones Fossilium Sectiles,' pl. viii., No. 91, König figures a remarkable fossil from the London clay of Sheppey, which is mentioned in the text as not certainly determinable, but generally regarded, by the anatomists who have examined it, as pertaining to some type of lizard. This specimen is preserved in the British Museum, and the author has determined that it is truly the imperfect head and pectoral arch of a Siluroid. The roof of the skull is preserved almost as far forwards as the middle of the frontals; the pectoral arch is in position, though slightly bent backwards; and the mass of ankylosed anterior vertebræ, with the basioccipital, is displaced downwards and thrown beneath the clavicles. All the bones are remarkably strong, and the exposed surfaces are ornamented with large tubercles. The head must have been originally somewhat deeper than broad, and the roof exhibits no flattening, but is strongly arched from side to side. Posteriorly, the supraoccipital projects in the usual manner, probably to meet a dermal plate upon the nape; and the post-temporal element seems to be merged with the bones of the postero-lateral angles of the cranium. It is impossible to determine the family-position of the genus in the usual manner, but the skulls of the West African *Auchenoglanis* and *Synodontis* appear to approach the fossil most closely. The provisional name of *Bucklandium diluvii* may be retained; and the fish is interesting as being the earliest undoubted Siluroid hitherto discovered.

7. *On the Origin of Graphite in the Archæan Rocks, with a Review of the alleged Evidence of Life on the Earth in Archæan Time.* By the Rev. A. IRVING, D.Sc., B.A., F.G.S.

Attention is drawn to the occurrence of carbon in meteorites and its supposed evidence of the pre-existence of vegetation, reference being made to the recent experiments of Mr. Lockyer. Möbius, Etheridge, Dr. Sterry Hunt, Dr. Dawson, and Dr. Geikie are referred to as having adopted a similar argument or else admitted the presence of graphite to be evidence in that direction. References are made to the writings of Credner and Von Hauer as to its actual occurrence in the archæan gneisses and schists. The general assumption of the *phytogenic origin* of graphite which has hitherto prevailed is found to derive no support from the specimens preserved in the national collection at South Kensington, since their structures can all be explained on mechanical principles. The only direct evidence of phytogenic origin is its occurrence in *later rocks* as an extreme carbonisation-product, but this clearly is no proof of such an origin for the archæan.

Other ways are then considered in which elementary graphitic carbon is produced without the intervention of organic life, such as

- (1) In the case of pig-iron.
- (2) The reduction of CO_2 by the alkali-metals and by magnesium, and the reduction of hydrocarbons by chlorine.
- (3) The dissociation of hydrocarbons by the spark-stream and by the contact-action of heated solid surfaces.

The last-mentioned process is conclusively demonstrated by the experimental results obtained during the last three months in the author's laboratory, carbon being copiously deposited from the hydrocarbons of common coal-gas by the simple contact-action of red-heated fragments of pumice (cf. the author's paper 'On Contact-action' read before Section B).

The known conditions under which acetylene, marsh-gas, and some more complex hydrocarbons can be formed synthetically were referred to, as well as the spectroscopic evidence of the existence of hydrocarbons in the heads of some comets. Such conditions probably obtained when the minerals of the archæan gneisses were formed by primary paramorphism from a state of dry fusion. It is therefore maintained that the necessarily phytogenic origin of archæan graphite is a pure assumption, and can no longer be urged in proof of Archæan organic life.

On the question of *animal life* the author takes his stand on the results of Möbius's investigations, which cannot be explained away, and considers that it is impossible to accept such slender evidence as has been produced of the organic origin of *Eozoon canadense* in the face of the overwhelming physical evidence (general and particular) against it.

The assumption by Sterry Hunt that the great beds of *iron-oxides* in the archæan rocks point to the pre-existence of vegetation, is shown to be without foundation; ferric oxide being the direct product of the combustion of iron-vapour in oxygen, and magnetic oxide the product of the reaction of steam on iron at high temperatures.

The *unfossiliferous limestones* (as well as the *quartzites* of the archæan and earlier Cambrian can be explained on purely chemical and physical principles, which are known and demonstrable; and there is no need here for the intervention of the agency of living organisms.

The sum of the whole matter is that we have no tangible and trustworthy evidence whatever of the existence on this globe of organic life in archæan time.

8. On some Devonian Cephalopods and Gasteropods.

By the Rev. G. F. WHIDBORNE, M.A., F.G.S.

The following new species occur at Woulborough or Lummaton, or, in the case of some of the Gasteropods, at Chudleigh: *Goniatites obliquus*, a large shell with open umbilicus, flat sloping sides and narrow flat back; *G. psittacinus*, a small tumid shell with closed umbilicus, rounded whorls, slightly curved sutures; *G. nuciformis*, with minute umbilicus and much broader back than the preceding; *G. aratus*, a flatter shell with small umbilicus and marked with four angulated sulci; *G. pentangularis*, with open spire, inner whorls ribbed, and section of whorls pentagonal; *G. Hughesii*, large and flat with closed umbilicus, evenly rounded back and minutely striated surface; *Cyrtoceras Leei*, a large curved conoidal form with more irregular and dilate lamellæ than *C. fimbriatum*, Ph.; *C. pulcherrimum*, unlike *C. reticulatum*, Ph., in having tubercles on the shoulder instead of ribs; *C. Vicarii*, having a broader section and much fewer tubercles than the last; *C. præclarus*, more involute and elliptical than the last, with wider mouth and oblique ridges crossed by distant striæ; *C. majestica*, large and smooth, with oval mouth, narrow chambers and imperfect spire; *Hercoceras inornatum*, differing from *H. subtuberculatum*, Sandb., in being smooth; *Orthoceras hastatum*, more conical and with fewer annulæ than *O. tubicinella*, Ph.; *O. Vicarii*, differing from *O. pulchellum*, F.A.Rö., in being round and not oval in section; *O. comatum*, which is *O. tubicinella*, Sandb., not Ph.; *Phragmoceras vasiformis*, which is rather less convex than Ph. subpyriforme, Mii.; *Ph. unguatum*, small and more arched than *C. cornucopiæ*, Sandb.; *Ph. Marri*, conical and transversely flattened, approaching *G. Conradi*, Barr.; *B. mundus*, with broad grooved keel and very transverse kidney-shaped mouth; *Euomphalus fenestralis*, which has a depressed spire with three ridges cancellated by numerous rings; *Pl. perversa*, a large sinistral shell, unlike *Pl. expansa* in having spiral striæ, a deeper suture, more convex whorls; *Pl. victrix*, which has an elevated spire, angulated whorls, central sinus band and a few spiral striæ; *Pl. fortilineata* = *Pl. imbricata*, M'Coy, not F.A.Rö.; *Pl. Chudleighensis*, separated from the preceding, having its spiral ridges crenulated and the sinus band much higher; *Littorina devonica*, having the general shape of *Purpura lapillus*, with eight spiral rows of tubercles which are largest near the suture; *Monodonta archon*, very large and trochiform with flat base and sides, linear suture and oblique growth lines; *Phorus philosophus*, with a low spire, wide umbilicus, and convex whorls bearing fragments of broken shells; *Macrocheilus tumescens*, a much more globular form than *M. subcostatus*, Schlot; *Turbo Pengellii*, unlike *T. subangulosus*, d'A. & de V., in its wider flatness above the shoulder; *Loxonema scalariodes*, very elongate, with its convex whorls crossed by discontinuous varices; *H. duplisulcata*, differing from *H. tenuisulcata* in possessing a series of subsidiary striæ; *Acroculia columbina*, a wide depressed form with fine waving longitudinal markings; *Melo-*

ptoma cordata, like *M. pileus*, Ph., but with loftier umbo and more angulated mouth; and *Chiton papilio*, which comes midway between *Ch. corrugatus*, Sandb., and *Ch. sagittalis*, Sandb.

The above are accompanied by *Orthoceras Oceani*, d'Orb. (= *O. cinctum*, Ph.), *O. tenuistriatum*, Mii., *O. subfusiforme*, d'A. & de V., *O. regulare*, Mii., *O. subannularis*, Mii., *B. lineatus*, Goldf. (= *B. striatus*, Ph.), *P. bifida*, Sandb. (= *B. Woodwardii*, Ph.), *Eu. serpula*, de Kon., *Eu. planorbis*, d'A. & de V., *Eu. lævis*, d'A. & de V., *Eu. rota*, Sandb., *Eu. decussatus*, Sandb., *Eu. germanus*, Ph. sp., *Eu. catenatus* (= *Eu. serpens*, Ph., Pal. Foss., fig. 172, f. and g. only), *Pl. D'Orbiguiana*, d'A. & de V., *Pl. subclathrata*, Sandb., *Pl. Lonsdalii*, d'A. & de V., *Pl. delphinuloides*, Schlot., *Pl. calculiformis*, Sandb., *Pl. trochoides* (= *Pl. monilifera*, Ph. Pal. Foss.), *Pl. distinguenda* (= *Pl. aspera*, Ph. Pal. Foss.), *N. deformis* Iow., *N. piligera*, Sandb., *T. multispira*, Sandb., *L. purpura*, d'A. & de V., *L. subcostata*, d'A. & de V., *Scalaria antiqua*, Mii., *M. subcostatus*, Schlot. (= *M. arcuatus*, Ph., and *M. elongatus*, Ph. *Scoliostoma texatum*, Ph. sp., *Sc. gracile*, Sandb., *Holopella tenuicostata*, Sandb., *H. tenuisukata*, Sandb., *H. piligera*, Sandb., *A. multiplicata*, Giebel, and *A. proava* Eichw.

9. On some Devonian Crustaceans.

By the Rev. G. F. WHIDBORNE, M.A., F.G.S.

Besides four or five species of trilobites and two ostracods already described from Woulborough and Lummaton, *Bronteus granulatus* (Goldf.) has occurred there, and the following new species:—*Prætus batillus*, which differs from *P. bohemicus*, Barr., in having a flatter glabella, more anterior eyes and longer cheek spines; *P. subfrontalis*, which differs from *P. frontalis*, Barr., in having a much squarer glabella; *P. audax*, which is like *P. cornutus*, Sandb., but without a perpendicular area in front of the glabella; *Cyphaspis ocellatus*, like *C. ceratophthalmus*, Sandb., but with long sabre-like cheek spines; *Lichas devonianus*, differing from *L. Haueri*, Barr., in having a wider head, larger eyes, surrounded with tubercles, and a more arched neck; *Acidaspis Robertsi*, with narrower side cheeks than the Bohemian type; *A. Hughesii*, having a bilobed tail surrounded by a flat border bearing aciculate spines; *Entomis peregrinus*, distinguishable from *E. pelagicus*, Barr., by the absence of a defined nodule; and *Bactropus decoratus*, dissimilar from *B. longipes*, Barr., in being much smaller and more coarsely striated.

The Cheirurus found at Lummaton is not *Ch. articulatus*, Mii., but a new species, *C. Pengellii*, differing from the former by having a shorter front lobe of the glabella.

10. On some Fossils of the Limestones of South Devon.

By the Rev. G. F. WHIDBORNE, M.A., F.G.S.

From the three localities of Woulborough, Lummaton, and Chudleigh, about 334 species are known, of which 104 are common to the two former places, and five occur in all three. Among these are *Orthis distorta*, Barr.; *Pterinea Wormii*, F. A. Rö., Pt. ala. Barr., *A. rudis* Ph., *A. plicatellus* (= *P. plicatus*, Ph., Pal. Fos.), *A. Cybele*, Barr., *A. consolans*, Barr., *P. lateralis*, Sow., *Hoplomytilus crassus*, Sandb., *Megalodon obliquus* (= *M. carinatus*, Ph., not Goldf.), *Pl. Vilmarensis*, d'A. and de V. *Pl. pugnans* (= *Pl. minax*, Ph.; Pal. Foss.), *H. interscapularis*, Ph. (including *H. depressus*, Aust.), *H. macrotatus*, Aust. (= *H. tuberculatus*, Ph. not Mill.), *H. ornatus*, Goldf., *Pl. fritillus*, Wiet. and Zieler., *H. Vicarii* (= *H. pentangularis*, Ph. not Mill.), *Pl. quintangulus* (= *Pl. pentangularis*, Aust. not Mill.), and *Rh. crenatus*, Goldf. ? *Receplaculites* sp. and *Serpula* ? *semiplicatus* Sandb.; and also the following, which are new: *Pterinea obovata*, a small deep species, like *Pt. texturata*, Ph., but without concentric lamellæ; *Pt. placida*, flatter and more angulated than the last, and with more distant ribs than *A. urbana*, Barr.; *Pt. dilatata*, which is larger and wider and with fewer and more distant ribs than the preceding, crossed by crowded growth lines; *Pt. crenatissima*, a longer shell with very anterior umbo,

and covered with fine granulated lines crossing minute rays; *Pt. bellula*, a species like *Pt. fasciculata*, Goldf., but with few alternating ribs crossed by distant zigzag striæ; *Aviculopecten hirundella*, separated from *Pt. texturata* by its shorter hinge line and finer reticulation (the right valve has transverse marks similar to those of *Pt. ala*. Barr.) *A. aviformis*, a flat recurved shell much produced and rounded behind, with very small umbo and wings; *A. comma*, similar to the preceding, but much smaller and with reticulated surface; *A. gracillimus*, a flat, elongate, sub-equilateral form, with minute umbo, notched anterior ear and close alternating ribs; *Mytilus Robertsii*, which is more ovoid and less produced in the postero-superior region than *M. dimidiatus*, Goldf.; *M. stultus*, a short, squarish form, with fine concentric striæ and a few stronger ones; *M. pinnoides*, which is shorter and has a more direct umbo than *M. uncinatus*, Eichw.; *Myalina elliptica*, a smooth, convex ovoid shell, differing from *Unio castor*, Eichw., in its more incurved umbo, and less dilate wings; *Megalodon columbinus*, separated from *M. carinatus*, Goldf., by its finer, regular plaits, more terminal umbo, and the contour of its elevated keel; *M. ? prominens*, larger than the last, and with coarser wavy plaits, loftier and more projecting umbo, and more oblique anterior margin; *Ctenodonta ? lepida*, a small, flat, transverse shell, which is narrower and more convex anteriorly than *P. modiolaris*, F. A. Rö.; *Cardiomorpha ? polita*, a flat, oblique species, unlike *A. damnoniensis*, Ph., in its smoothness and its shorter hinge-line; *Cypricardia neglecta*, with fewer, stronger ribs and more definite wing than *M. scalaris*, Ph., *C. guttata*, with fewer plaits and rounder indentations than *C. crenistria*, Sandb.; *C. ensiformis*, a much flatter and wider shell than *C. neglecta*, and with more and finer plaits; *Edmondia ? dubia*, a large, wide convex shell, with a recurved anterior umbo, deep area and close, indistinct, bifurcating growth, lines; *Hexacrinus perarmatus*, with calix, like *H. macrotatus*, Aust., but covered with sharp, regular, non-confluent tubercles; *H. microglyphicus*, with a convex calix, very long basals, and fine ornamentation; *Platycrinus aberrans*, with trilobed attachment, elongate calix, three squarish basal, four or five long radials, intercalated with one large and one small subsidiary anal; *Haplocrinus decipiens*, a minute crinoid, having a short calix with an elevated conical summit, with key-shaped grooves for the arms; *Tricælocrinus ? Leei*, with shorter limbs and shallower excavations than *T. Woodmani*, Mate and Worthen; and *Serpula ? devonica*, a long, straight, smooth, and cylindrical tube.

SUB-SECTION C.

1. Mineralogical Evolution. By T. STERRY HUNT, LL.D., F.R.S.

In a paper read by the author in 1887, before the Geological Section of the British Association for the Advancement of Science, on The Elements of Primary Geology, it was said that 'the transformation of the primitive igneous material of the earth's crust through the action of air and water, aided by internal heat, presents a mineralogical evolution not less regular, constant, and definite in its results than the evolution apparent in the organic kingdoms.'¹ The details of this complex evolutionary process, as explained by what the writer has named the crenitic hypothesis, have been elsewhere set forth at length, on more than one occasion, and involve the whole chemical history of the various mineral species which enter into the constitution of rock-masses, but especially their relations to subterranean changes under the influence of heated water, and to atmospheric action. As we have pointed out, the transformation of basalt into the hydrous porodic body known as palagonite, and the subsequent partial conversion of this into a crystalline zeolite, as described by Bunsen, furnishes a significant illustration of the process under consideration.

The stability of silicated species under atmospheric influences is very variable,

¹ *Transactions*, p. 704; also *Geological Magazine*, November 1887.

some being readily decomposed, and others very permanent; the indifference or chemical resistance, moreover, increasing with the hardness or mechanical resistance. These two qualities vary, for species of analogous constitution, directly as their condensation; while for species of similar condensation and hardness, the chemical indifference increases as alumina takes the place of the ordinary protoxyd-bases, lime, magnesia, ferrous oxyd, and alkalies—a fact readily explained by the comparative insolubility of alumina and aluminous silicates in atmospheric waters. The less partial action of dilute fluorhydric acid on the various silicates shows more clearly than the atmospheric process, the relation of condensation to chemical indifference. This relation may be made evident by a few examples. The condensation being inversely as the so-called atomic volume, we find that when calculated by a simple formula (elsewhere given by the author) for all silicates and oxyds this value, represented by $v (=p \div d)$ for the various feldspars and scapolites, for nephelite, iolite, and petalite, equals 6.8–6.2; for the muscovitic or non-magnesian micas, 5.9–5.6; for garnet, epidote, zoisite, and the various tourmalines, 5.4–5.3; for staurolite and spodumene, 4.9; and for andalusite, topaz, fibrolite, and cyanite, 5.0–4.5, approximately. Comparing with these the common protoxyd-silicates, we find for wollastonite and willemite, $v = 6.6$; for amphibole, 5.9; for pyroxene and enstatite, 5.5; for chrysolite, 5.4–5.3; and for phenakite, 4.6. In the sub-aërial decay of crystalline rocks, while felspars and scapolites among aluminiferous silicates are kaolinised, the micas, notwithstanding their laminated structure, are much less readily changed, and garnet, epidote, tourmaline, andalusite, and topaz are found unaltered, with the quartz, corundum, spinel, cassiterite, and magnetite left behind by the decay of the feldspathic rocks—a process in which even amphibole, pyroxene, and chrysolite share. ‘The greater stability of those [silicates] which belong to the more condensed types is shown in their superior resistance to decay, and is thus of geological significance.’

While the above are examples of the varying resistance to the atmospheric influences of carbon dioxyd and water combined, other changes less well known take place in silicates by the subterranean action of watery solutions, where a greater insolubility determines the formation of certain softer hydrated magnesian and aluminous species by epigenesis from harder and more condensed species. The production of these epigenic products, as was said in 1885, is due to their ‘chemical stability under the circumstances,’ and it was added, ‘The constancy in composition and the wide distribution of pinite show that it is a compound readily formed and of great stability. Such being its character, it might be expected to occur as a frequent product of the aqueous changes of other and less stable silicates. It is met with in veinstones in the shape of crystals of nephelite, iolite, scapolite, felspars, and spodumene, from each of which it is supposed to have been formed by epigenesis. Its frequent occurrence as an epigenic product is one of the many examples to be met with in the mineral kingdom of the law of “the survival of the fittest.” It is, however, difficult to assign such an origin to beds of this [described as dysyntribite and parophite], which are probably the results of original deposition or of diagenesis.’

Mr. E. A. Ridsdale, who during the present year (1888) has done good service by publishing a suggestive essay called ‘Notes on Inorganic Evolution,’ speaks of the production and conservation of more stable species, as above described, as a gradual ‘selection of inert forms,’ and further, as ‘a survival of the most inert.’ But as inertness consists in stability, and in fitness to resist alike the chemical and the mechanical agencies which destroy other species, it is evident that his phraseology is but another statement of the formula of ‘the survival of the fittest.’

The great principle of the change of the mineral matters which existed in former conditions of our planet, into other forms more stable under the altered conditions of later ages, is but an extension to the mineral kingdom of the laws already recognised in astronomical and biological development. As was written in 1884, ‘That a great law presided over the development of the crystalline rocks was from the first my conviction, but until the confusion which a belief in the miracles of metamorphism, metasomatism, and vulcanism had introduced into geology had been dispelled, the discovery of such a law was impossible.’ To this we may add

that 'the great successive groups of stratiform crystalline rocks mark necessary stages in the mineralogical evolution of the planet'; and that the principles which we have elsewhere laid down will help us 'to recognise the existence and the necessity of an orderly lithological development in time.' The reader who desires to follow the questions here raised will find them discussed in the author's 'Mineral Physiology and Physiography, (Boston, 1886), at much length in chapters V., VI., VII., and VIII., and further noticed in the Appendix, p. 688, where will be found references to previous pages here cited.

2. *Report on the Microscopic Structure of the Older Rocks of Anglesey.*
See Reports, p. 367.

3. *On a probable Cause of Contortions of Strata.*
By CHARLES RICKETTS, M.D., F.G.S.

The amount of compression to which the crust of the earth would be subjected as the effect of subsidence, by the presence of faults and other causes, as well as by the secular cooling of its mass (Rev. O. Fisher, 'Phil. Mag.,' Jan. 1888), is too inconsiderable to develop the great contortions and foldings certain strata have undergone.

When accompanied by cleavage, the distortion of contained fossils and the displacement of included rock fragments (the flat sides lying parallel to the cleavage planes), indicate that the change occurred whilst the clay deposits were in an unconsolidated or plastic condition.

It is suggested that these flexures may be dependent on irregular pressure, caused by the local distribution of larger and heavier particles on accumulations of unconsolidated muddy deposits, in a similar manner to what may be demonstrated by spreading layers of clay of various colours, dried and reduced to powder, in a trough; when, on the admission of water, the clay has become plastic, sand is heaped on some special part and extra weight applied, which in the experiment is necessary. The heavier substance subsides into the plastic mass, and at the same time the clay beds are squeezed outwards, causing the layers underneath to be formed into films, which are still continuous with those on the sides, though these are rendered considerably thicker than in their original state and are curved into folds, even to reversal of the beds, representing on a small scale what are frequently met with in stratified rocks. The experiment so coincides with natural phenomena that it is reasonable to expect it will prove to be a true and frequent cause of the contortions of strata.

4. *On the Temperature at which Beryl is decolorised.¹*
By J. JOLY, M.A., B.E.

Experiments on some translucent green and yellow beryls from Glencullen, Co. Dublin, show that these beryls are almost entirely deprived of colour when exposed for one hour to a temperature of 357° C., i.e., the temperature of boiling mercury at atmospheric pressure. The loss of colour takes place whether the beryls are out of contact with the air or not. It was found further that exposure to a temperature of 230° C. for the space of 30 hours effected a marked loss of colour. In all cases the crystals retain their translucency. They have shown no signs of regaining colour during a lapse of three years since the date of the experiments.

The author suggests that this observation may bear on the history of the containing granite subsequent to the formation of beryl if the colour of the latter be regarded as indicating a major limit to the changes of temperature experienced by the rock.

5. *On the Occurrence of Iolite in the Granite of County Dublin.*¹

By J. JOLY, M.A., B.E.

Iolite, not previously noticed in Irish granite, has been found by the author in the granite of Glencullen. It occurs as a microscopical but abundant inclusion in a substance of felspathic nature which is to be found interpenetrating prisms of beryl. Its presence is confined, apparently, to the felspar so intermixed with beryl. The iolite is in twelve-sided basal prisms, showing the faces I , $i-1$, $i-3$, $i-1$, O , in size up to 0.1 mm. in length, transparent, colourless viewed singly, and presenting a vivid and beautiful object in the polarising microscope. Characteristic features are the basal angles of 150° , 120° or 60° ; its generally symmetrical extinction on elongated rectangular sections and the transverse cleavage on such sections. A foliation or plating on O , and an oblique twining line parallel to I , are also frequently met with. Occasionally the crystals occur in radiating groups. Enclosures are rare, generally glass.

6. *An Igneous Succession in Shropshire.*

By W. W. WATTS, M.A., F.G.S.

The author described the succession of Igneous Rocks in the Shelve and Corndon district in Shropshire.

1. There is a series of Andesitic ashes, interbedded at two principal horizons in the Ordovician sequence. These have a percentage of silica varying from 66–60.

2. Then come three sets of intrusive masses. *a.* Andesites (59–54 per cent. of silica). These are intruded into Ordovician rocks, and never touch the Silurian of the district. *b.* Dolerites (51–48 per cent. of silica) which are post-Silurian in date. *c.* Picrites (41–34 per cent. of silica) of later date. These are undoubtedly rocks intermediate in age and composition, but it is difficult to be quite sure of this where the differences in composition are so slight. One, however—the dolerite of Llanfawr—is a very basic dolerite, coming between the normal dolerites and picrites. In minerals a similar transition is to be noted. The Andesites are rich in Hypersthene, the Dolerites rather richer in Augite, while Olivine and Brown Mica come in in the Picrites. The author believed, though he had no means of certainly proving it, that the felspars became more basic in the more basic rocks, but certainly there were *different* felspars in some of the different members of the series. Another curious point was that the mineral aggregates in glomeroporphyritic Andesites are practically pieces of the ophitic dolerites. The determination of the specific gravities of these rocks gave a similar sequence, the least dense rocks having been erupted first and the denser last. Each of the eruptive rocks occurred in laccolites along the main anticlinal line of the district and also in dykes and along fault lines.

SECTION D.—BIOLOGY.

PRESIDENT OF THE SECTION.—W. T. THISELTON-DYER, C.M.G., M.A., B.Sc.,
F.R.S., F.L.S.

THURSDAY, SEPTEMBER 6.

The PRESIDENT delivered the following Address:—

BEFORE we commence the formal business of the Section, I propose to invite your attention to several points which have suggested themselves to me from a consideration of the present position and progress of the study of botany in this country.

It is not so very long ago that at English universities, at least, the pursuit of botany was regarded rather as an elegant accomplishment than as a serious occupation. This is the more remarkable because at every critical point in the history of botanical science the names of our countrymen will be found to occupy an honourable place in the field of progress and discovery. In the seventeenth century Hooke and Grew laid the foundations of the cell theory, while Millington, by discovering the function of stamens, completed the theory of the flower. In the following century Morison first raised ferns from spores, Lindsay detected the fern prothallus, Ray laid the foundations of a natural classification, Hales discovered root-pressure, and Priestley the absorption of carbon dioxide and the evolution of oxygen by plants. In the early part of the present one we have Knight's discovery of the true cause of geotropism, Daubeny's of the effect upon the processes of plant-life of rays of light of different refrangibility, and finally, the first description of the cell-nucleus by R. Brown. I need not attempt to carry the list through the last half-century. I have singled out these discoveries as striking landmarks, the starting-points of important developments of the subject. It is enough for my purpose to show that we have always had an important school of botany in England, which has contributed at least its share to the general development of the science.

I think at the moment, however, we have little cause for anxiety. The academic chairs throughout the three kingdoms are filled, for the most part, with young, enthusiastic, and well-trained men. Botany is everywhere conceded its due position as the twin branch with zoology of biological science. We owe to the enlightened administration of the Oxford University Press the possession of a Journal which allows of the prompt and adequate publication of the results of laboratory research. The excellent work which is being done in every part of the botanical field has received the warm sympathy of our colleagues abroad. I need only recall to your recollection, as a striking evidence of this, the remarkable gathering of foreign botanists, which will ever make the meeting of this Association at Manchester a memorable event to all of us. The reflection rises sadly to the mind that it can never be repeated. Not many months, as you know, had passed before the two most prominent figures in that happy assemblage had been removed from us by the inexorable hand of death. In Asa Gray we miss a figure which we could never admit belonged wholly to the other side of the Atlantic. In technical botany we recognised him as altogether in harmony with the methods of work and standard of excellence of our own most distinguished taxonomists. But, apart from this, he

had that power of grasping large and far-reaching ideas, which, I do not doubt, would have brought him distinction in any branch of science. We owe to him the classical discussion of the facts of plant distribution in the Northern Hemisphere, which is one of the corner-stones of modern geographical botany. He was one of the earliest of distinguished naturalists who gave his adhesion to the theory of Mr. Darwin. A man of simple and sincere piety, the doctrine of descent never presented any difficulty to him. He will remain in our memories as a figure endowed with a sweetness and elevation of character which may be compared even with that of Mr. Darwin himself.

In De Bary we seem to have suffered no less a personal loss than in the case of Gray. Though, before last year, I do not know that he had ever been in England, so many of our botanists had worked under him that his influence was widely felt amongst us. And it may be said that this was almost equally so in every part of the civilised world. His position as a teacher was in this respect probably unique, and the traditions of his methods of work must permanently affect the progress of botany, and, indeed, have an even wider effect. This is not the occasion to dwell on each of his scientific achievements. It is sufficient to say that we owe to him the foundations of a rational vegetable pathology. He first grasped the true conditions of parasitism in plants, and not content with working out the complex phases of the life-history of the invading organism, he never lost sight of the conditions which permitted or inhibited its invasion. He treated the problem, whether on the side of the host or of the parasite, as a whole, as a biological problem, in fact, in the widest sense. It is this thorough grasp of the conditions of the problem that give such a peculiar value to his last published book, the 'Lectures on Bacteria,' an admirable translation of which we owe to Professor Balfour. To this I shall have again to refer. I must content myself with saying now, that in this and all his work there is that note of highest excellence which consists in lifting detail to the level of the widest generality. To a weak man this is a pitfall, in which a firm grasp of fact is lost in rash speculation. But when, as in De Bary's case, a true scientific insight is inspired by something akin to genius, the most fruitful conceptions are the result. Yet De Bary never sacrificed exactness to brilliancy, and to the inflexible love of truth which pervaded both his work and his personal intercourse we may trace the secret of the extraordinary influence which he exerted over his pupils.

As the head of one of the great national establishments of the country devoted to the cultivation of systematic botany, I need hardly apologise for devoting a few words to the present position of that branch of the science. Of its fundamental importance I have myself no manner of doubt. But as my judgment may seem in such a matter not wholly free from bias, I may fortify myself with an opinion which can hardly be minimised in that way. The distinguished chemist, Professor Lothar Meyer, perhaps the most brilliant worker in the field of theoretical chemistry, finds himself, like the systematic botanist, obliged to defend the position of descriptive science. And he draws his strongest argument from biology. 'The physiology of plants and animals,' he tells us, 'requires systematic botany and zoology, together with the anatomy of the two kingdoms: each speculative science requires a rich and well-ordered material, if it is not to lose itself in empty and fruitless fantasies.' No one, of course, supposes that the accumulation of plant specimens in herbaria is the mere outcome of a passion for accumulating. But to do good systematic work requires high qualities of exactitude, patience, and judgment. As I attempted to show on another occasion, the world is hardly sensible of the influence which the study of the subject has had on its affairs. The school of Jeremy Bentham has left an indelible mark on the social and legislative progress of our own time. Mill tells us that 'the proper arrangement of a code of laws depends on the same scientific conditions as the classifications in natural history; nor could there,' he adds, 'be a better preparatory discipline for that important function than the principles of a natural arrangement, not only in the abstract, but in their actual application to the class of phenomena for which they were first elaborated, and which are still the best school for learning their use.' He further tells us that of this Jeremy Bentham was perfectly

aware, and that his 'Fragment on Government' contains clear and just views on the meaning of a natural arrangement which reflect directly the influence of Linnæus and Jussieu. Mill himself possessed a competent knowledge of systematic botany, and therefore was well able to judge of its intellectual value. For my part, I do not doubt that precisely the same qualifications of mind which made Jeremy Bentham a great jurist, enabled his nephew to attain the eminence he reached as a botanist. As a mere matter of mental gymnastic, taxonomic science will hold its own with any pursuit. And, of course, what I say of botany is no less true of other branches of natural history. Mr. Darwin devoted eight or nine years to the systematic study of the *Cirripedia*. 'No one,' he himself tells us, 'has a right to examine the question of species who has not minutely described many.' And Mr. Huxley has pointed out, in the admirable memoir of Mr. Darwin which he has prepared for the Royal Society, that, the acquirement of an intimate and practical knowledge of the process of species-making . . . 'was of no less importance to the author of the "Origin of Species" than was the bearing of the Cirripede work upon the principles of a natural classification.'

At present the outlook for systematic botany is somewhat discouraging. France, Germany, and Austria no longer possess anything like a school in the subject, though they still supply able and distinguished workers. That these are, however, few, may be judged from the fact that it is difficult to fill the place of the lamented Eichler in the direction of the Botanic Garden and Herbarium at Berlin. Outside our own country, Switzerland is the most important seat of general systematic study to which three generations of De Candolles have devoted themselves. The most active centres of work at the moment are, however, to be found in our own country, in the United States, and in Russia. And the reason is, in each case, no doubt the same. The enormous area of the earth's surface over which each country holds sway brings to them a vast amount of material which peremptorily demands discussion.

No country, however, affords such admirable facilities for work in systematic botany as are now to be found in London. The Linnean Society possesses the Herbarium of Linnæus; the Botanical Department of the British Museum is rich in the collections of the older botanists; while at Kew we have a constantly increasing assemblage of material, either the results of travel and expeditions or the contributions of correspondents in different parts of the empire. A very large proportion of this has been worked up. But I am painfully impressed with the fact that the total of our available workers bears but a small proportion to the labour ready to their hands.

This is the more a matter of concern, because for the few official posts which are open to botanists at home or abroad a practical knowledge of systematic botany is really indispensable. For suitable candidates for these one naturally looks to the universities. And so far, I am sorry to say, in great measure one looks in vain. It would be, no doubt, a great impulse to what is undoubtedly an important branch of national scientific work if fellowships could occasionally be given to men who showed some aptitude for it. But these should not be mere prizes for undergraduate study, but should exact some guarantee that during the tenure of the fellowship the holder would seriously devote himself to some definite piece of work. At present, undoubtedly, the younger generation of botanists show a disposition to turn aside to those fields in which more brilliant and more immediate results can be attained. Their neglect of systematic botany brings to some extent its own Nemesis. A first principle of systematic botany is that a name should denote a definite and ascertainable species of plant. But in physiological literature you will find that the importance of this is often overlooked. Names are employed which are either not to be found in the books, or they are altogether misapplied. But if proper precautions are taken to ascertain the accurate botanical name of a plant, no botanist throughout the civilised world is at a loss to identify it.

But precision in nomenclature is only the necessary apparatus of the subject. The data of systematic botany, when properly discussed, lend themselves to very important generalisations. Perhaps those which are yielded by the study of

geographical distribution are of the most general interest. The mantle of vegetation which covers the surface of the earth, if only we could rightly unravel its texture, would tell us a good deal about geological history. The study of geographical distribution, properly handled, affords an independent line of attack upon the problem of the past distribution of land and sea. It would probably never afford sufficient data for a complete independent solution of the problem; but it must always be extremely useful as a check upon other methods. Here, however, we are embarrassed by the enormous amount of work which has yet to be accomplished. And unfortunately this is not of a kind which can be indefinitely postponed. The old terrestrial order is fast passing away before our eyes. Everywhere the primitive vegetation is disappearing as more and more of the earth's surface is brought into cultivation or, at any rate, denuded of its forests.

A good deal, however, has been done. We owe to the indomitable industry of Mr. Bentham and of Sir Ferdinand Mueller a comprehensive flora of Australia, the first large area of the earth's surface of which the vegetation has been completely worked out. Sir Joseph Hooker, in his retirement, has pushed on within sight of completion the enormous work of describing so much of the vast Indo-Malayan flora as is comprised within British possessions. To the Dutch botanists we owe a tolerably complete account of the Malayan flora proper. But New Guinea still remains botanically a *terra incognita*, and till within the last year or two the flora of China has been an absolute blank to us. A committee of the British Association (whose report will be presented to you) has, with the aid of a small grant of money, taken in hand the task of gathering up the scanty data which are available in herbaria and elsewhere. This has stimulated European residents in China to collect more material, and the fine collections which are now being rapidly poured in upon us will, if they do not overwhelm us by their very magnitude, go a long way in supplying data for a tentative discussion of the relations of the Chinese flora to that of the rest of Asia. I do not doubt that this will in turn explain a good deal that is anomalous in the distribution of plants in India. The work of the committee has been practically limited to Central and Eastern China. From the west, in Yunnan, the French botanists have received even more surprising collections, and these supplement our own work in the most fortunate manner. I have only to add for Asia Boissier's '*Flora Orientalis*,' which practically includes the Mediterranean basin. But I must not omit the invaluable report of Brigade-Surgeon Aitchison on the collections made by him during the Afghan Delimitation Expedition. This has given an important insight into the vegetation of a region which had never previously been adequately examined. Nor must I forget the recent publication of the masterly report by Professor Bayley Balfour on the plants collected by himself and Schweinfurth in Socotra, an island with which the ancient Egyptians traded, but the singularly anomalous flora of which was almost wholly unknown up to our time.

The flora of Africa has been at present but imperfectly worked up, but the materials have been so far discussed as to afford a tolerably correct theory of its relations. The harvest from Mr. Johnston's expedition to Kilimanjaro was not as rich as might have been hoped. Still, it was sufficient to confirm the conclusions at which Sir Joseph Hooker had arrived, on very slender data, as to the relations of the high-level vegetation of Africa generally. The flora of Madagascar is perhaps, at the moment, the most interesting problem which Africa presents to the botanist. As the rich collections, for which we are indebted to Mr. Baron and others, are gradually worked out, it can hardly be doubted that it will be necessary to modify in some respects the views which are generally received as to the relation of the island to the African continent. My colleague, Mr. Baker, communicated to the York Meeting of the Association the results which, up to that time, he had arrived at, and these subsequent material has not led him to modify. The flora as a whole presents a large proportion of endemic genera and species, pointing to isolation from a very ancient date. The tropical element is, however, closely allied to that of Tropical Africa and of the Mascarene Islands, and there is a small infusion of Asiatic types which do not extend to Africa. The high-level flora, on the other hand, exhibits an even closer affinity with that temperate flora the ruins of which

are scattered over the mountainous regions of Central Africa, and which survives in its greatest concentration at the Cape.

The American botanists at Harvard are still systematically carrying on the work of Torrey and Gray in the elaboration of the flora of Northern America. The Russians are, on their part, continually adding to our knowledge of the flora of Northern and Central Asia. The whole flora of the North Temperate Zone can only be regarded substantially as one. The identity diminishes southwards and increases in the case of the Arctic and Alpine regions. A collection of plants brought us from high levels in Corea by Mr. James might, as regards a large proportion of the species, have been gathered on one of our own Scotch hills.

We owe to the munificence of two English men of science the organisation of an extensive examination of the flora and fauna of Central America and the publication of the results. The work, when completed, can hardly be less expensive than that of the results of the 'Challenger' voyage, which has severely taxed the liberality of the English Government. The problems which geographical distribution in this region present will doubtless be found to be of a singularly complicated nature, and it is impossible to overestimate the debt of gratitude which biologists of all countries must owe to Messrs. Godman and Salvin when their arduous undertaking is completed. I am happy to say that the botanical portion, which has been elaborated at Kew, is all but finished.

In South America, I must content myself with referring to the great 'Flora Brasiliensis,' commenced by Martius half a century ago, and still slowly progressing under the editorship of Professor Urban at Berlin. Little discussion has yet been attempted of the mass of material which is enshrined in the mighty array of volumes already published. But the travels of Mr. Ball in South America have led him to the detection of some very interesting problems. The enormous pluvial denudation of the ancient portions of the continent has led to the gradual blending of the flora of different levels with sufficient slowness to permit of adaptive changes in the process. The tropical flora of Brazil, therefore, presents an admixture of modified temperate types which gives to the whole a peculiar character not met with to the same degree in the tropics of the old world. On the other hand, the comparatively recent elevation of the southern portion of the continent accounts, in Mr. Ball's eyes, for the singular poverty of its flora, which we may regard indeed as still in progress of development.

The botany of the 'Challenger' expedition, which was also elaborated at Kew, brought for the first time into one view all the available facts as to the floras of the older oceanic islands. To this was added a discussion of the origin of the more recent floras of the islands of the Western Pacific, based upon material carefully collected by Professor Moseley and supplemented by the notes and specimens accumulated with much judgment by Dr. Guppy. For the first time we were enabled to get some idea how a tropical island was furnished with plants and to discriminate the littoral element due to the action of oceanic currents from the interior forest almost wholly due to frugivorous birds. The recent examination of Christmas Island by the English Admiralty has shown the process of island flora-making in another stage. The plants collected by Mr. Lister prove, as might be expected, to be closely allied to those of Java. But the effect of isolation has begun to tell; and I learn from my colleague, Professor Oliver, that the plants from Christmas Island cannot be for the most part exactly matched with their congeners from Java, but yet do not differ sufficiently to be specifically distinguished. We have here, therefore, it appears to me, a manifest case of nascent species.

The central problem of systematic botany I have not as yet touched upon: this is to perfect a natural classification. Such a classification, to be perfect, must be the ultimate generalisation of every scrap of knowledge which we can bring to bear upon the study of plant affinity. In the higher plants experience has shown that we can obtain results which are sufficiently accurate for the present without carrying our structural analysis very far. Yet even here, the correct relations of the Gymnosperms would never have been ascertained without patient and minute microscopic study of the reproductive processes. Upon these, indeed, the correct classification of the Vascular Cryptogams wholly depends, and generally, as we

descend in the scale, external morphology becomes more and more insecure as a guide, and a thorough knowledge of the minute structure and life history of each organism becomes indispensable to anything like a correct determination of its taxonomic position. The marvellous theory of the true nature of Lichens would never have been ascertained by the ordinary methods of examination which were held to be sufficient by lichenologists.

The final form of every natural classification—for I have no doubt that the general principles I have laid down are equally true in the field of zoology—must be to approximate to the order of descent. For the Theory of Descent became an irresistible induction as soon as the idea of a natural classification had been firmly grasped.

In regard to flowering plants we owe, as I have said, the first step in a natural classification to our own great naturalist John Ray, who divided them into Monocotyledons and Dicotyledons. The celebrated classification of Linnæus was avowedly purely artificial. It was a temporary expedient, the provisional character of which no one realised more thoroughly than himself. He, in fact, himself gave us one of the earliest outlines of a truly natural system. Such a system is based on affinity, and we know of no other explanation of affinity than that which is implied in the word, namely, common parentage. No one finds any difficulty in admitting that, where a number of individual organisms closely resemble one another, they must have been derived from the same stock. I allow that, in cases where external form is widely different, the conclusion to one who is not a naturalist is by no means so obvious. But in such cases it rests on the profound and constant resemblance of internal points of structure. Anyone who studies the matter with a perfectly open mind finds it impossible to draw a line. If genetic relationship or heredity is admitted to be the explanation of affinity in the most obvious case, the stages are imperceptible, when the evidence is fairly examined, by which the same conclusion is inevitable, even in cases where at the first glance it seems least likely.

This leads me to touch on the great theory which we owe to Mr. Darwin. That theory, I need hardly say, was not merely a theory of descent. This had suggested itself to naturalists in the way I have indicated long before. What Mr. Darwin did was to show how by perfectly natural causes the separation of living organisms into races which at once resemble and yet differ from one another so profoundly came about. Heredity explains the resemblance; Mr. Darwin's great discovery was that variation worked upon by natural selection explained the difference. That explanation seems to me to gather strength every day and to continually reveal itself as a more and more efficient solvent of the problems which present themselves to the student of natural history. At the same time I am far from claiming for it the authority of a scientific creed or even the degree of certainty which is possessed by some of the laws of astronomy. I only affirm that as a theory it has proved itself a potent and invaluable instrument of research. It is an immensely valuable induction; but it has not yet reached such a position of certitude as has been attained by the Law of Gravitation, and I have myself, in the field of botany, felt bound to protest against conclusions being drawn deductively from it without being subjected to the test of experimental verification. This attitude of mine, which I believe I share with most naturalists, must not, however, be mistaken for one of doubt. Of doubt as to the validity of Mr. Darwin's views I have none; I shall continue to have none till I come across facts which suggest doubt. But that is a different position from one of absolute certitude.

It is therefore without any dissatisfaction that I observe that many competent persons have, while accepting Mr. Darwin's theory, set themselves to criticise various parts of it. But I must confess that I am disposed to share the opinion expressed by Mr. Huxley, that these criticisms really rest on a want of a thorough comprehension.

Mr. Romanes has put forward a view which deserves the attention due to the speculations of a man of singular subtlety and dialectic skill. He has startled us with the paradox that Mr. Darwin did not after all put forth, as I conceive it was his own impression he did, a theory of the origin of species, but only of adaptations.

And inasmuch as Mr. Romanes is of opinion that specific differences are not 'even generally' adaptive, while those of genera are, it follows that Mr. Darwin only really accounted for the origin of the latter, while for an explanation of the former we must look to Mr. Romanes himself. For my part, however, I am altogether unable to accept the premises, and therefore fail to reach the conclusion. Specific differences, as we find them in plants, are for the most part indubitably adaptive, while the distinctive characters of genera and of higher groups are rarely so. Let anyone take the numerous species of some well-characterised English genus, for example *Ranunculus*; he will find that one species is distinguished by having creeping stems, one by a tuberous root, one by floating leaves, another by drawn-out submerged ones, and so on. But each possesses those common characters which enable the botanist almost at a glance, notwithstanding the adaptive disguise, to refer them to the common genus *Ranunculus*. It seems to me quite easy to see, in fact, why specific characters should be usually adaptive, and generic not so. Species of any large genus must, from the nature of things, find themselves exposed to any but uniform conditions. They must acquire, therefore, as the very condition of their existence, those adaptive characters which the necessities of their life demand. But this rarely affects those marks of affinity which still indicate their original common origin. Probably these were themselves once adaptive, but they have long been overlaid by newer and more urgent modifications. Still Nature is ever conservative, and these reminiscences of a bygone history persist; significant to the systematic botanist as telling an unmistakable family story, but far removed from the stress of a struggle in which they no longer are called upon to bear their part.

Another episode in the Darwinian theory is, however, likely to occupy our attention for some time to come. The biological world now looks to Professor Weissmann as occupying the most prominent position in this field of speculation. His theory of the continuity of the germ-plasm has been put before English readers with extreme lucidity by Professor Moseley. That theory, I am free to confess, I do not find it easy to grasp clearly in all its concrete details. At any rate, my own studies do not furnish me with sufficient data for criticising them in any adequate way. It is, however, bound up with another theory—the non-inheritance of acquired characters—which is more open to general discussion. If with Weissmann we accept this principle, it cannot be doubted that the burden thrown on natural selection is enormously increased. But I do not see that the theory of natural selection itself is in any way impaired in consequence.

The question, however, is, are we to accept the principle? It appears to me that it is entirely a matter of evidence. It is proverbially difficult to prove a negative. In the analogous case of the inheritance of accidental mutilations Mr. Darwin contents himself with observing that we should be 'cautious in denying it.' Still I believe that, though a great deal of pains has been devoted to the matter, there is no case in which it has been satisfactorily proved that a character acquired by an organism has been transmitted to its descendants; and there is, of course, an enormous bulk of evidence the other way.

The consideration of this point has given rise to what has been called the new Lamarckism. Now Lamarck accounted for the evolution of organic nature by two principles—the tendency to progressive advancement and the force of external circumstances. The first of these principles appears to me, like Nägeli's internal modifying force, to be simply substituting a name for a thing. Lamarck, like many other people before him, thought that the higher organisms were derived from others lower in the scale, and he explained this by saying that they had a tendency to be so derived. This appears to me much as if we explained the movement of a train from London to Bath by attributing it to a tendency to locomotion. Mr. Darwin lifted the whole matter out of the field of mere transcendental speculation by the theory of natural selection, a perfectly intelligible mechanism by which the result might be brought about. Science will always prefer a material *modus operandi* to anything so vague as the action of a tendency.

Lamarck's second principle deserves much more serious consideration. To be perfectly fair we must strip it of the crude illustrations with which he hampered

it. To suggest that a bird became web-footed by persistently stretching the skin between its toes, or that the neck of a giraffe was elongated in the perpetual attempt to reach the foliage of trees, seems almost repugnant to common sense. But the idea that changes in climate and food—i.e. in the conditions of nutrition generally—may have some slow but direct influence on the organism seems, on a superficial view, so plausible that the mind is very prone to accept it. Mr. Darwin has himself frankly admitted that he thought he had not attached sufficient weight to the direct action of the environment. Yet it is extremely difficult to obtain satisfactory evidence of effects produced in this way. Hoffmann experimented with much pains on plants, and the results were negative. And Mr. Darwin confessed that Hoffmann's paper had 'staggered' him.

Organic evolution still, therefore, seems to me to be explained in the simplest way as the result of variation controlled by natural selection. Now both these factors are perfectly intelligible things. Variation is a mere matter of everyday observation, and the struggle for existence which is the cause, of which natural selection is the effect, is equally so. If we state in a parallel form the Lamarckian theory, it amounts to a tendency controlled by external forces. It appears to me that there is no satisfactory basis of fact for either factor. The practical superiority of the Darwinian over the Lamarckian theory is, as a working hypothesis, immeasurable.

The new Lamarckian school, if I understand their views correctly, seek to re-introduce Lamarck's 'tendency.' The fact has been admitted by Mr. Darwin himself that variation is not illimitable. No one, in fact, has ever contended that any type can be reached from any point. For example, as Weissmann puts it, 'under the most favourable circumstances a bird can never become transformed into a mammal.' It is deduced from this that variation takes place in a fixed direction only, and this is assumed to be due to an innate law of development, or, as Weissmann has termed it, a 'phyletic vital force.' But the introduction of any such directive agency is superfluous, because the limitation of variability is a necessary consequence of the physical constitution of the varying organism.

It is supposed, however, by many people that a necessary part of Mr. Darwin's theory is the explanation of the phenomenon of variation itself. But really this is not more reasonable than to demand that it should explain gravitation or the source of solar energy. The investigation of any one of these phenomena is a matter of first-rate importance. But the cause of variation is perfectly independent of the results that flow from it when subordinated to natural selection.

Though it is difficult to establish the fact that external causes promote variation directly, it is worth considering whether they may not do so indirectly. Weissmann, like Lamarck before him, has pointed out, as others have also done, the remarkable persistence of the plants and animals of Egypt; and the evidence of this is now even stronger. We owe, at Kew, to the kindness of Dr. Schweinfurth, a collection of specimens of plants from Egyptian tombs which are said to be as much as 4,000 years old. They are still perfectly identifiable, and, as one of my predecessors in this chair has pointed out, they differ in no respect from their living representatives in Egypt at this day. The explanation which Lamarck gave of this fact 'may well,' says Sir Charles Lyell, 'lay claim to our admiration.' He attributed it, in effect, to the persistence of the physical geography, temperature, and other natural conditions. The explanation seems to me adequate. The plants and animals, we may fairly assume, were, 4,000 years ago, as accurately adjusted to the conditions in which they then existed as the fact of their persistence in the country shows that they must be now. Any deviation from the type that existed then would either, therefore, be disadvantageous or indifferent. In the former case it would be speedily eliminated, in the latter it would be swamped by cross-breeding. But we know that if seeds of these plants were introduced into our gardens we should soon detect varieties amongst their progeny. Long observation upon plants under cultivation has always disposed me to think that a change of external conditions actually stimulated variation, and so gave natural selection wider play and a better chance of re-establishing the adaptation of the organism to them. Weissmann explains the remarkable fact that organisms may for thousands of years reproduce themselves unchanged by the principle of the

persistence of the germ-plasm. Yet it seems hard to believe that the germ-plasm, while enshrined in the individual whose race it is to perpetuate, and nourished at its expense, can be wholly indifferent to all its fortunes. It may be so, but in that case it would be very unlike other living elements of organised beings.

I am bound, however, to confess that I am not wholly satisfied with the data for the discussion of this question which practical horticulture supplies. That the contents of our gardens do exhibit the results of variation in a most astonishing degree no one will dispute. But for scientific purposes any exact account of the treatment under which these variations have occurred is unfortunately usually wanting. A great deal of the most striking variation is undoubtedly due to wide crossing, and these cases must, of course, be eliminated when the object is to test the independent variation of the germ-plasm. Hoffmann, whose experiments I have already referred to, doubts whether plants do as a matter of fact vary more under cultivation than in their native home and under natural conditions. It would be very interesting if this could be tested by the concerted efforts of two cultivators, say, for example, in Egypt and in England. Let some annual plant be selected, native of the former country, and let its seed be transmitted to the latter. Then let each cultivator select any variations that arise in regard to some given character; set to work, in fact, exactly as any gardener would who wanted to 'improve' the plant, but on a preconcerted plan. A comparison of the success which each obtained would be a measure of the effect of the change of the environment on variability. If it proved that, as Hoffmann supposed, the change of conditions did not affect what we may call the rate of variation, then, as Mr. Darwin remarks in writing to Professor Semper, 'the astonishing variations of almost all cultivated plants must be due to selection and breeding from the varying individuals. This idea,' he continues, 'crossed my mind many years ago, but I was afraid to publish it, as I thought that people would say, "How he does exaggerate the importance of selection!"' From an independent consideration of the subject I also find my mind somewhat shaken about it. Yet I feel disposed to say with Mr. Darwin, 'I still *must* believe that changed conditions give the impulse to variability, but that they act *in most cases* in a very indirect manner.'

Whatever conclusions we arrive at on these points, everyone will agree that one result of the Darwinian theory has been to give a great impulse to the study of organisms, if I may say so, as 'going concerns.' Interesting as are the problems which the structure, the functions, the affinity, or the geographical distribution of a plant may afford, the living plant in itself is even more interesting still.

Every organ will bear interrogation to trace the meaning and origin of its form and the part it plays in the plant's economy. That there is here an immense field for investigation there can be no doubt. Mr. Darwin himself set us the example in a series of masterly investigations. But the field is well-nigh inexhaustible. The extraordinary variety of form which plants exhibit has led to the notion that much of it may have arisen from indifferent variation. No doubt, as Mr. Darwin has pointed out, when one of a group of structures held together by some morphological or physiological *nexus* varies, the rest will vary correlatively. One variation then may, if advantageous, become adaptive, while the rest will be indifferent. But it appears to me that such a principle should be applied with the greatest caution, and from what I have myself heard fall from Mr. Darwin, I am led to believe that in the later years of his life he was disposed to think that every detail of plant structure had some adaptive significance, if only the clue could be found to it. As regards the forms of flowers an enormous body of information has been collected, but the vegetative organs have not yielded their secret to anything like the same extent. My own impression is that they will be found to be adaptive in innumerable ways which at present are not even suspected. At Kew we have probably a larger number of species assembled together than are to be found anywhere on the earth's surface. Here, then, is ample material for observation and comparison. But the adaptive significance will doubtless often be found by no means to lie on the surface. Who, for example, could possibly have guessed by inspection the purpose of the glandular bodies on the leaves of *Acacia sphærocephala* and on the pulvinus of *Cecropia peltata* which Belt in the one case, and Fritz Müller in the other have

shown to serve as food for ants? So far from this explanation being farfetched, Belt found that the former 'tree is actually unable to exist without its guard,' which it could not secure without some attraction in the shape of food. One fact which strongly impresses me with a belief in the adaptive significance of vegetative characters is the fact that in almost identical forms they are constantly adopted by plants of widely different affinity. If such forms were without significance one would expect them to be infinitely varied. If, however, they are really adaptive, it is intelligible that different plants should independently avail themselves of the same appliances and expedients.

Although this country is splendidly equipped with appliances for the study of systematic botany, our universities and colleges fall far behind a standard which would be considered even tolerable on the Continent in the means of studying morphological and physiological botany or of making researches in these subjects. There is not at the moment anywhere in London an adequate botanical laboratory, and though at most of the universities matters are not quite so bad, still I am not aware of any one where it is possible to do more than give the routine instruction or to allow the students, when they have passed through this, to work for themselves. It is not easy to see why this should be, because on the animal side the accommodation and appliances for teaching comparative anatomy and physiology are always adequate and often palatial. Still less explicable to me is the tendency on the part of those who have charge of medical education to eliminate botanical study from the medical curriculum, since historically the animal histologists owe everything to botanists. In the seventeenth century, as I have already mentioned, Hooke first brought the microscope to the investigation of organic structure, and the tissue he examined was cork. Somewhat later, Grew, in his 'Anatomy of Plants,' gave the first germ of the cell-theory. During the eighteenth century the anatomists were not merely on a hopelessly wrong tack themselves, but they were bent on dragging botanists into it also. It was not till 1837, a little more than fifty years ago, that Henle saw that the structure of epithelium was practically the same as that of the *parenchyma plantarum* which Grew had described 150 years before. Two years later Schwann published his immortal theory, which comprised the ultimate facts of plant and animal anatomy under one view. But it was to a botanist, Von Mohl, that, in 1846, the biological world owed the first clear description of protoplasm, and to another botanist, Cohn (1851), the identification of this with the sarcode of zoologists.

Now the historic order in discovery is not without its significance. The path which the first investigators found most accessible is doubtless that which beginners will also find easiest to tread. I do not myself believe that any better access can be obtained to the structure and functions of living tissues than by the study of plants. However, I am not without hopes that the serious study of botany in the laboratory will be in time better cared for. I do not hesitate to claim for it a position of the greatest importance in ordinary scientific education. All the essential phenomena of living organisms can be readily demonstrated upon plants. The necessary appliances are not so costly, and the work of the class-room is free from many difficulties with which the student of the animal side of biology has to contend.

Those, however, who have seriously devoted themselves to the pursuit of either morphological or physiological botany need not now be wholly at a loss. The splendid laboratory on Plymouth Sound, the erection of which we owe to the energy and enthusiasm of Professor Ray Lankester, is open to botanists as well as to zoologists, and affords every opportunity for the investigation of marine plants, in which little of late years has been done in this country. At Kew we owe to private munificence a commodious laboratory in which much excellent work has already been done. And this Association has made a small grant in aid of the establishment of a laboratory in the Royal Botanic Garden at Peradeniya, in Ceylon. It may be hoped that this will afford facilities for work of the same kind as has yielded Dr. Treub such a rich harvest of results in the Buitenzorg Botanic Garden in Java.

Physiological botany, as I have already pointed out, is a field in which this

country in the past has accomplished great things. It has not of late, however, obtained an amount of attention in any way proportionate to that devoted to animal physiology. In the interests of physiological science generally, this is much to be deplored; and I believe that no one was more firmly convinced of this than Mr. Darwin. Only a short time before his death, in writing to Mr. Romanes on a book that he had recently been reading, he said that the author had made 'a gigantic oversight in never considering plants; these would simplify the problem for him.' This goes to the root of the matter. There is, in my judgment, no fundamental biological problem which is not exhibited in a simpler form by plants than animals. It is possible, however, that the distaste which seems to exist amongst our biologists for physiological botany may be due in some measure to the extremely physical point of view from which it has been customary to treat it on the Continent. It is owing in great measure to the method of Mr. Darwin's own admirable researches that in this country we have been led to a more excellent way. The work which has been lately done in England seems to me full of the highest promise. Mr. Francis Darwin and Mr. Gardiner have each in different directions shown the entirely new point of view which may be obtained by treating plant phenomena as the outcome of the functional activity of protoplasm. I have not the least doubt that by pursuing this path English research will not merely place vegetable physiology, which has hitherto been too much under the influence of Lamarckism, on a more rational basis, but that it will also sensibly react, as it has done often before, on animal physiology.

There is no part of the field of physiological botany which has yielded results of more interest and importance than that which relates to the action of ferments and fermentation; and I could hardly give you a better illustration of the purely biological method of treating it. I believe that these results, wonderful and fascinating as they are, afford but a faint indication of the range of those that are still to be accomplished. The subject is one of extreme intricacy, and it is not easy to speak about it briefly. To begin with, it embodies two distinct groups of phenomena which have in reality very little which is essential in common.

What are usually called ferments are perhaps the most remarkable of all chemical bodies, for they have the power of effecting very profound changes in the chemical constitution of other substances, although they may be present in very minute quantity; but—and this is their most singular and characteristic property—they themselves remain unchanged in the process. It may be said without hesitation that the whole nutrition of both animals and plants depends on the action of ferments. Organisms are incapable of using solid nutrient matter for the repair and extension of their tissues; this must be first brought into a soluble form before it can be made available, and this change is generally brought about by the action of a ferment. Animal physiology has long been familiar with the part played by ferments, and it may be said that no small part of the animal economy is made up of organs required either for the manufacture of ferments or for the exposure of ingested food to their action. It may seem strange at first sight to speak of analogous processes taking place in plants. But it must be remembered that plant nutrition includes two very distinct stages. Certain parts of plants build up, as everyone knows, from external inorganic materials substances which are available for the construction of new tissues. It might be supposed that these are used up as fast as they are formed. But it is not so; the life of the plant is not a continuous balance of income and expenditure. On the contrary, besides the general maintenance of its structure, the plant has to provide from time to time for enormous resources to meet such exhausting demands as the renewal of foliage, the production of flowers, and the subsequent maturing of fruit.

In such cases the plant has to draw on an accumulated store of solid food which has rapidly to be converted into the soluble form in which alone it is capable of passing through the tissues to the seat of consumption. And I do not doubt for my part that in such cases ferments are brought into play of the same kind and in the same way as in the animal economy. Take such a simple case as a potato tuber. This is a mass of cellular tissue, the cells of which are loaded with starch. We may either dig up the tuber and eat the starch ourselves or we may leave it in

the ground, in which case it will be consumed in providing material for the growth of a potato-plant next year. But the processes by which the insoluble starch is made available for nutrition are, I cannot doubt, closely similar in either case.

When we inquire further about these mysterious and all-important bodies, the answer we can give is extremely inadequate. It is very difficult to obtain them in amount sufficient for analysis or in a state of purity. We know, however, that they are closely allied to albuminoids and contain nitrogen in varying proportion. Papain, which is a vegetable ferment derived from the fruit of the papaw, and capable of digesting most animal albuminoids, is said to have the same ultimate composition as the pancreatic ferment and as peptones, bodies closely allied to proteids; the properties of all three bodies are, however, very different. It seems clear, nevertheless, that ferments must be closely allied to proteids, and, like these bodies, they are, no doubt, directly derived from protoplasm.

I need not remind you that, unlike other constituents of plant tissues, protoplasm, as a condition of its vitality, is in a constant state of molecular activity. The maintenance of this activity involves the supply of energy, and this is partly derived from the waste of its own substance. This 'self-decomposition' of the protoplasm liberates energy, and in doing so gives rise to a number of more stable bodies than protoplasm. Some of these are used up again in nutrition; others are thrown aside and are never drawn again into the inner circle of vital processes. In the animal organism, where the strictest economy of bulk is a paramount necessity, they are promptly got rid of by the process of excretion. In the vegetable economy these residual products usually remain. And it is for this reason, I may point out, that the study of the chemistry of plant-nutrition appears to me of such immense importance. The record of chemical change is so much more carefully preserved; and the probability of our being able to trace the course it has followed is consequently far more likely to be attended with success.

This preservation in the plant of the residual by-products of protoplasmic activity no doubt accounts for the circumstance which otherwise is extremely perplexing—the profusion of substances which we meet with in the vegetable kingdom to which it is hard to attribute any useful purpose. It seems probable that ferments, in a great many cases, belong to the same category. I imagine that it is in some degree accidental that some of them have been made use of, and thus the plant has been able to temporarily lock up accumulations of food to be drawn upon in future phases of its life with the certainty that they would be available. Without the ferments the key of the storehouse would be lost irretrievably.

Plants, moreover, are now known to possess ferments, and the number will doubtless increase to which it is difficult to attribute any useful function. Papain, to which I have already alluded, abounds in the papaw; but it is not easy to assign to it any definite function; still less is it easy, on teleological grounds, to account for the rennet ferment contained in the fruits of an Indian plant, *Withania coagulans*, and admirably investigated by Mr. Sheridan Lea.

Having dwelt so far on the action of ferments, we may now turn to fermentation and that other kind of change in organic matter called 'putrefaction,' which is known to be closely allied to fermentation. Ferments and fermentation, as I have already remarked, have very little to do with one another; and it would save confusion and emphasise the fact if we ceased to speak of ferments but used some of the alternative names which have been proposed for them, such as *zymases* or *enzymes*.

The classical case of fermentation, which is the root of our whole knowledge of the subject, is that of the conversion of sugar into alcohol. Its discovery has everywhere accompanied the first stages of civilisation in the human race. Its details are now taught in our text-books; and I should hardly hope to be excused for referring to it in any detail if it were not necessary for my purpose to draw your attention more particularly to one or two points connected with it.

Let us trace what happens in a fermenting liquid. It becomes turbid, it froths and effervesces, the temperature sensibly increases; this is the first stage. After this it begins to clear, the turbidity subsides as a sediment; the sugar which

the fluid at first contained has in great part disappeared, and a new ingredient, alcohol, is found in its place.

It is just fifty years ago that the great Dutch biologist Schwann made a series of investigations which incontrovertibly demonstrated that both fermentation and putrefaction were due to the presence of minute organisms which live and propagate at the expense of the liquids in which they produce as a result these extraordinary changes. The labours of Pasteur have confirmed Schwann's results, and—what could not have been foreseen—have extended the possibilities of this field of investigation to those disturbances in the vital phenomena of living organisms themselves which we include under the name of 'disease,' and which, no one will dispute, are matters of the deepest concern to every one of us.

Now, at first sight, the conversion of starch into sugar by means of diastase seems strikingly analogous to the conversion of sugar into alcohol. It is for this reason that the phenomena have been so long associated. But it is easy to show that they are strikingly different. Diastase is a chemical substance of obscure composition it is true, but inert and destitute of any vital properties, nor is it affected by the changes it induces. Yeast, on the other hand, which is the active agent in alcoholic fermentation, is a definite organism; it enormously increases during the process, and it appears to me impossible to resist the conclusion that fermentation is a necessary concomitant of the peculiar conditions of its life. Let me give you a few facts which go to prove this. In the first place, you cannot ferment a perfectly pure solution of sugar. The fermentible fluid must contain saline and nitrogenous matters necessary for the nutrition of the yeast protoplasm. In pure sugar the yeast starves. Next, Schwann found that known protoplasmic poisons, by killing the yeast-cells, would prohibit fermentation. He found the same result to hold good of putrefaction, and this is the basis of the whole theory of antiseptics. Nor can the action of yeast be attributed to any ferment which the yeast secretes. It is true that pure cane-sugar cannot be fermented, and that yeast effects the inversion of this, as it is called, into glucose and lævulose. It does this by a ferment which can be extracted from it, and which is often present in plants. But you can extract nothing from yeast which will do its peculiar work apart from itself. Helmholtz made the crucial experiment of suspending a bladder full of boiled grape-juice in a vat of fermenting must; it underwent no change; and even a film of blotting-paper has been found a sufficient obstacle to its action. We are driven, then, necessarily to the conclusion that in the action of 'ferments' or zymases we have to do with a chemical—i.e. a purely physical process; while in the case of yeast we encounter a purely physiological one.

How, then, is this action to be explained? Pasteur has laid stress on a fact which had some time been known, that the production of alcohol from sugar is a result of which yeast has not the monopoly. If ripening fruits, such as plums, are kept in an atmosphere free from oxygen, Bérard found that they, too, exhibit this remarkable transformation; their sugar is converted appreciably into alcohol. On the other hand, Pasteur has shown that, if yeast is abundantly supplied with oxygen, it feeds on the sugar of a fermentible fluid without producing alcohol. But, under the ordinary circumstances of fermentation, its access to oxygen is practically cut off; the yeast, then, is in exactly the same predicament as the fruit in Bérard's experiment. Sugar is broken up into carbon dioxide and alcohol in an amount far in excess of the needs of mere nutrition. In this dissociation it can be shown that an amount of energy is set free in the form of heat equal to about one-tenth of what would be produced by the total combustion of an equivalent amount of grape-sugar. If the protoplasm of the yeast could, with the aid of atmospheric oxygen, completely decompose a unit of grape-sugar, it would get ten times as much energy in the shape of heat as it could get by breaking it up into alcohol and carbon dioxide. It follows, then, that to do the same amount of growth in either case, it must break up ten times as much sugar without a supply of oxygen as with it. And this throws light on what has always been one of the most remarkable facts about fermentation—the enormous amount of change which the yeast manages to effect in proportion to its own development.

There are still two points about yeast which deserve attention before we dismiss

it. When a fermenting liquid comes to contain about 14 per cent. of alcohol, the activity of the yeast ceases, quite independently of whether the sugar is used up or not. In other cases of fermentation the same inhibiting effect of the products of fermentation is met with. Thus lactic fermentation soon comes to an end unless calcium carbonate or some similar substance be added, which removes the lactic acid from the solution as fast as it is formed.

The other point is that in all fermentations, besides what may be termed the primary products of the process, other bodies are produced. In the case of alcoholic fermentation the primary bodies are alcohol and carbon dioxide; the secondary, succinic acid and glycerine. Delpino has suggested that these last are residual products derived from that portion of the fermentible matter which is directly applied to the nutrition of the protoplasm.

Yeast, itself the organism which effects the remarkable changes on which I have dwelt, is somewhat of a problem. It is clear that it is a fungus, the germs of which must be ubiquitous in the atmosphere. It is difficult to believe that the simple facts, which are all we know about it, constitute its entire life history. It is probably a transitory stage of some more complicated organism.

I can only briefly refer to putrefaction. This is a far more complex process than that which I have traced in the case of alcoholic fermentation. In that nitrogen is absent, while it is an essential ingredient in albuminoids, which are the substances which undergo putrefactive changes. But the general principles are the same. Here, too, we owe to Schwann the demonstration of the fact that the effective agents in the process are living organisms. If we put into a flask a putrescible liquid such as broth, boil it for some time, and during the process of boiling plug the mouth with some cotton-wool, we know that the broth will remain long unchanged, while if we remove the wool putrescence soon begins. Tyndall has shown that, if we conduct the experiment on one of the high glaciers of the Alps, the cotton-wool may be dispensed with. We may infer, then, that the germs of the organisms which produce putrefaction are abundant in the lower levels of the atmosphere and are absent from the higher. They are wafted about by currents of air; but they are not imponderable, and in still air they gradually subside. Dr. Lodge has shown that air is rapidly cleared of suspended dust by an electric discharge, and this, no doubt, affords a simple explanation of the popular belief that thunderous weather is favourable to putrefactive changes.

Cohn believes that putrefaction is due to an organism called *Bacterium Termo*, which plays in it the same part that yeast does in fermentation. This is probably too simple a statement; but the general phenomena are nevertheless similar. There is the same breaking down of complex into simpler molecules; the same evolution of gas, especially carbon dioxide; the same rise of temperature. The more or less stable products of the process are infinitely more varied, and it is difficult, if not impossible, to say, in the present state of our knowledge, whether in most cases they are the direct outcome of the putrefactive process, or residual products of the protoplasmic activity of the organisms which induce it. Perhaps, on the analogy of the higher plants, in which some of them also occur, we may attribute to the latter category certain bodies closely resembling vegetable alkaloids; these are called ptomains, and are extremely poisonous. Besides such bodies, bacteria undoubtedly generate true ferments and peculiar colouring matters. But there are in most cases of putrefaction a profusion of other substances, which represent the various stages of the breaking up of the complex proteid molecule, and are often themselves the outcome of subsidiary fermentations.

These results are of great interest from a scientific point of view. But their importance at the present moment in the study of certain kinds of disease can hardly be exaggerated. I have already mentioned Henle as having first found the true clue to animal histology in the structure of plants. As early as 1840 the same observer indicated the grounds for regarding contagious diseases as due to living organisms. I will state his argument in the words of De Bary, whose 'Lectures on Bacteria,' the last work which we owe to his gifted hand, I can confidently recommend to you as a luminous but critical discussion of a vast mass of difficult and conflicting literature.

It was, of course, clear that contagion must be due to the communication of infectious particles or contagia. These contagia, although at the time no one had seen them, Henle pointed out, 'have the power, possessed, as far as we know, by living creatures only, of growing under favourable conditions, and of multiplying at the expense of some other substance than their own, and therefore of assimilating that substance.' Henle enforced his view by comparison with the theory of fermentation, which had then been promulgated by Schwann. But for many years his views found no favour. Botanists, however, as in so many other cases, struck on the right path, and from about the year 1850 steady progress, in which De Bary himself took a leading part, was made in showing that most of the diseases of plants are due to parasitic infection. The reason of this success was obvious: the structure of plants make them more accessible to research, and the invading parasites are larger than animal contagia. On the animal side all real progress dates from about 1860, when Pasteur, having established Schwann's theory of fermentation on an impregnable basis, took up Henle's theory of living contagia.

The only risk now is that we may get on too fast. To put the true theory of any one contagious disease on as firm a basis as that of alcoholic fermentation is no easy matter to accomplish. But I believe that this is, notwithstanding a flood of facile speculation and imperfect research, slowly being done.

There are two tracts in the body which are obviously accessible to such minute organisms as bacteria, and favourable for their development. These are the alimentary canal and the blood. In the case of the former there is evidence that every one of us possesses quite a little flora of varied forms and species. They seem for the most part, in health, to be comparatively innocuous; indeed, it is believed that they are ancillary to and aid digestion. But it is easy to see that other kinds may be introduced, or those already present may be called into abnormal activity, and fermentative processes may be set up of a very inconvenient kind. These may result in mere digestive disorder, or in the production of some of those poisonous derivatives of proteids of which I have spoken, the effect of which upon the organism may be most disastrous.

The access of bacteria to the blood is a far more serious matter. They produce phenomena the obvious analogy of which to fermentative processes has led to the resulting diseases being called zymotic. Take, for example, the disease known as 'relapsing fever.' This is contagious. After a period of incubation, violent fever sets in, which lasts for something less than a week, is then followed by a period of absence, to be again followed in succession by one or more similar attacks, which ultimately cease. Now you will observe that the analogy to a fermentative process is very close. The period of incubation is the necessary interval between the introduction of the germ and its vegetative multiplication in sufficient numbers to appreciably affect the total volume of the blood. The rise in temperature and the limited duration of the attack are equally, as we have seen, characteristic of fermentative processes, while the bodily exhaustion which always follows fever is the obvious result of the dissipation by the ferment organisms of nutritive matter destined for the repair of tissue-waste. During the presence of this fever there is present in the blood an organism, *Spirochæte Obermeieri*, so named after its discoverer. This disappears when the fever subsides. It is found that if other individuals are inoculated with blood taken from patients during the fever attack, the disease is communicated, but that this is not the case if the inoculation is made during the period of freedom. The evidence then seems clear that this disease is due to a definite organism. The interesting point, however, arises, why does the fever recur, and why eventually cease? The analogy of fermentation leads to the hypothesis that, as in the case of yeast, the products of its action inhibit after a time the further activity of the *Spirochæte*. The inhibiting substance is, no doubt, eventually removed partially from the blood by its normal processes of depuration, and the surviving individuals of *Spirochæte* can then continue their activity, as in lactic fermentation. With regard to the final cessation of the disease, there are facts which may lead one to suppose that in this as in other cases sufficient of the inhibiting substance ultimately remains in the organism to protect it against any further outbreak of activity on the part of the *Spirochæte*.

Here we have an example of a disease which, though having a well-marked zymotic character, is comparatively harmless. In Anthrax, which is known to be due to *Bacillus anthracis*, we have one which is, on the contrary, extremely fatal. I need not enter into the details. It is sufficient to say that there is reason to believe that the *Bacillus* produces, as one of those by-products of protoplasmic destruction to which I have already alluded, a most virulent poison. But the remarkable thing is that this *Bacillus*, which can be cultivated externally to the body, if kept at a heightened temperature, can be attenuated in its virulence. It drops, in fact, the excretion of the poison. It is then found that, if injected into the blood, it does no mischief, and, what is more extraordinary, if the *Bacillus* in its most lethal form is subsequently introduced, it too has lost its power. The explanation of the immunity in this case is entirely different to that which was suggested by a consideration of the facts of relapsing fever. The researches of Metschnikoff have led to the hypothesis that in the present case the white blood-corpuscles destroy the *Bacillus*. When they first come into contact with these in their virulent form they are unable to touch them. But if they have been educated by first having presented to them the attenuated form, they find no difficulty in grappling with the malignant. This is a very remarkable view. I should not have put it before you had there not been solid reasons for regarding the idea of the education of protoplasm with scientific respect. The plasmodia of the myxomycetes, which consist of naked protoplasm, are known to become habituated to food which they at first reject, and the researches of Beyerinck on the disease known as 'gumming' in plants have apparently shown that healthy cells may be taught, as it were, to produce a ferment which otherwise they would not excrete.

If Metschnikoff's theory be true, we have a rational explanation of vaccination and of preventive inoculation generally. It is probably, however, not the only explanation. And the theory of the inhibitive action upon itself of the products of the ferment-organism's own activity is still being made the basis of experiment. In fact, the most recent results point to the possibility of obtaining protection by injecting into the blood substances artificially obtained entirely independent of the organisms whose development they inhibit.

It is impossible for me to touch on these important matters at any greater length, but I doubt if the theory of fermentation, as applied to the diseases of organisms, has as yet more than opened its first page. It seems to me possible that, besides the rational explanation of zymotic diseases, it may throw light on others where, owing to abnormal conditions, the organism, as in the case of Bérard's plums, is itself the agent in its own fermentative processes.

And now I must conclude. I have led you, I am afraid, a too lengthy and varied a journey in the field of botanical study. But to sum up my argument. I believe I have shown you that at the bottom of every great branch of biological inquiry it has never been possible to neglect the study of plants; nay, more, that the study of plant-life has generally given the key to the true course of investigation. Whether you take the problems of geographical distribution, the most obscure points in the theory of organic evolution, or the innermost secrets of vital phenomena, whether in health or disease, not to consider plants is still, in the words of Mr. Darwin, 'a gigantic oversight, for these would simplify the problem.'

6. *On Adelphotaxy: an undescribed Form of Irritability.*
By Professor MARCUS M. HARTOG, D.Sc., M.A.

In *Achlya*, a genus of Saprolegnieæ, the zoospores lie in the sporangium before liberation closely appressed together, with their long axes parallel, instead of showing the rotatory hustling movements of other species. In liberation, instead of separating and swimming off, each on its own account, they remain near the mouth of the sporangium, each in turn edging its way in between those that have already escaped with its narrower flagellate (anterior end inwards). They thus form a hollow sphere, each zoospore rotating round its long axis (radial to the sphere) before encysting in its place. The only explanation that will fit these phenomena is that these zoospores are endowed with a peculiar irritability in virtue of which they tend to place themselves close together side by side, with their long axes parallel. This irritability is only exerted at a short distance; for, if a zoospore be pushed as little as its long diameter away, whether by accident or design, it fails to find its place, but swims off to and fro, instead of rotating *in situ*, before encysting.

In a critical review, now in the press, of a paper by Rothert, I have given the name '*adelphotaxy*' to this form of irritability, consisting in the tendency of spontaneously motile cells to assume definite positions with regard to their fellows.

Leaving aside the kindred question of tissue-formation and the processes in the embryo-sac of Phanerogams, adelphotaxy is of rare occurrence in the Vegetable Kingdom. Two good instances occur in the Chlorophytes. In *Pediastrum* the contents of each cell of the flat disc break up into 16 (or 32) zoospores, which swarm in the cell, and then unite edge to edge to form a new disc. So in each cell of a *Hydrodictyon* the many thousand zoospores unite end to end to form a new network with hexagonal meshes.

In many of the Myxomycetes the plasmodia aggregate together before fructification to form the compound masses termed æthalia; possibly even the very formation of plasmodia may be regarded as a mode of adelphotaxy.

We may perhaps go a step further and ascribe the parallel or converging courses of *Fungus hyphæ* to form mycelium strings, fruit bodies, and pseudo-parenchyma as extreme cases of adelphotaxy.

I think this principle affords a ready explanation of many cases of cellular aggregation in the animal embryo, and the formation of the spermatophores of many animals, notably Limicolous Worms.

The relations of sexual and isogamous union of gametes to adelphotaxy are obvious; for, though in some cases of sexual union chemotaxy has been shown by Pfeffer to be involved in bringing the active gamete from a distance, that will not cover the actual fusion of the two cells.

6. *On the Irruption of Syrrhaptes paradoxus.*
By Professor NEWTON, M.A., F.R.S.

The author began by observing that 25 years before, almost to a day, he had made a communication with the very same title to the Section at Newcastle, and had then been bold enough to anticipate a recurrence of the irruption of which he then treated, a full account of which appeared in 'The Ibis' for 1864. After briefly pointing out the peculiarities of this singular form of bird, and tracing what was known of its early history, especially of its appearance in Europe prior to the first great irruption of 1863, he proceeded to notice the two small and less known visitations of 1872 and 1876. In the former of these it had only been observed in two localities—one on the coast of Northumberland, the other on that of Ayrshire—in both cases in the month of June, though in neither was any specimen procured. In the latter (1876) it was observed in three localities—one being near Winterton, in Norfolk (in May), another near Modena, in Italy (in June), and the third in the county Wicklow, in Ireland (in October). The irruption of the present year had been on a scale at least as large as that of 1863, if not larger—certainly the number of observations was greatly in excess. It had also taken place fully a month earlier. From the information at present in his possession it had extended further to the southward—in Italy to Orvieto, and in Spain (which country had been for the first time reached) to the Albufera of Valencia; and to the westward—to Belmullet, in the county Mayo; but at present it seemed to have fallen short as regards its northern limits, though very possibly time would prove that localities quite as far towards the north as on the former occasions (the Nord Fjord, in Norway, and the Færoes) had been attained. The limits of all the irruptions from 1859 to 1888 were shown on a map, and in this way it was evident that the general direction of all was practically identical. The discovery of the 'radiant point' (which might be assumed to be beyond the Caspian Sea) was very desirable, and on this matter the author hoped trustworthy information might be received from Russian observers. With regard to the causes which had led to these extraordinary movements, he wished to express himself cautiously; but their apparent regularity inclined him to think that they were not due to any 'convulsion of Nature,' as some persons supposed, but rather, as he had before suggested, to the natural overflow of a redundant population. When more complete information had been obtained he hoped to treat this irruption at length in 'The Ibis' for the year 1889 in some such way as he had treated that of 1863.

7. *Remarks on some Teleostean Ova, and their Development.*
By J. T. CUNNINGHAM, B.A., F.R.S.E.

The ovum of *Solea vulgaris* has a diameter of 1.46 to 1.47 mm. Its perivitelline space is small. There are a large number of very minute oil-globules aggregated in irregular groups on the surface of the yolk, at first mostly near the

edge of the blastoderm, later chiefly at the sides of the embryo. There is a single layer of separate vitelline masses, at first beneath the blastoderm, later forming a superficial layer over the whole yolk.

Neither the *Solea*, sp. A, nor *Solea*, sp. B, of Raffaele ('Mitt. Zool. Stat. Neapel,' Bd. viii.) is the ovum of *Solea vulgaris*.

The ovum of *Solea variegata* has a diameter of 1.36 mm. The oil-globules are separate and not united in groups, and they are larger than in *Solea vulgaris*; otherwise the ova of the two species are similar. No. 1 of Raffaele's 'specie indeterminate' is probably the ovum of *Solea variegata*.

The ovum of *Pleuronectes microcephalus* has a diameter of 1.36 to 1.37 mm. The yolk is perfectly homogeneous, the perivitelline space small. The larva, which hatches in seven, eight, or nine days, has a multicolumnar notochord, the mouth not open, the rectum in contact with the yolk. Chromatophores, black and yellow in colour, are present over the sides of the body, in the median fin fold, and on the surface of the yolk.

The ovum of the mackerel is 1.22 mm. in diameter; the perivitelline space is small; the yolk has a single large oil-globule, which is at first movable, but afterwards fixed beneath the posterior end of the embryo. Black chromatophores develop on the body of the embryo and on the deeper surface of the oil-globule, and others of a green colour behind the eye and on the side of the embryo above the oil-globule.

It was suggested that there is a close connection between the presence of one or more oil-globules in a pelagic ovum and the abundance of oil in the body of the parent. The pilchard is oily, and its ovum has an oil-globule; the herring is less oily, and its ovum is without that structure.

It was argued that the space round the heart is a part of the body cavity, continuous posteriorly with the lateral body cavities; while the space between the yolk-sac and the yolk, with which the heart is in open communication, corresponds to the vitelline veins in those Teleostean ova where the latter exist. This venous space seems to be the segmentation cavity continued and remaining open throughout development; at the same time the cavity has been altered morphologically when the heart develops by the appearance of mesoblastic cells on the surface of the periblast, these cells being the dendritic chromatophores on the surface of the yolk visible in the living larva, but not to be traced in transverse sections. Thus Ryder ('U.S. Fish Commissioners' Report' for 1882) was wrong in calling the space round the heart the pericardium, and the venous space both segmentation cavity and body cavity; while Shipley ('Quart. Journ. Mic. Sci.' 1887) gives an account of the parts in *Petromyzon* which closely agrees with the above description of them in Teleostei, the differences being that he found no mesoblastic cells on the surface of the yolk in *Petromyzon*, and found that the coelem had not developed in the lateral mesoblast posterior to the heart at the time that it had developed an anterior ventral portion around that organ.

The following Papers were read:—

PHYSIOLOGICAL DEPARTMENT.

1. *On the Physiological Bearing of Waist-belts and Stays.*
By Professor ROY, M.D., F.R.S., and J. G. ADAMI, M.A.

In the course of an investigation upon the work of the heart in health and in disease, certain facts were observed by the authors which throw not a little light upon the physiological bearing of waist-belts and girdles. By means of an instrument devised by them—a Cardiometer—they have been enabled to register very

accurately the changes of volume in, and the amount of blood propelled by, the heart in a given time under varying conditions. Experimenting upon the dog, they found that even slight compression of the abdomen caused an increase in volume of the heart, and that with this a greatly increased amount of blood passed through the heart in a given time, the increase being often thirty or even forty per cent. more in some cases. These phenomena can be explained without difficulty. The abdominal vessels are capable of containing all, and more than all, the blood in the organism. Slight compression of the abdomen will, without disturbing the arterial supply, drive out from the abdominal veins and venous capillaries a large amount of blood; and this blood so driven out will, as long as the compression continues, be of use for the other regions of the body—for the brain, muscles, &c.

Now the functional activity of any organ depends directly upon its blood-supply. With increase in the arterial blood-supply of any part, other things being equal, the activity and power of work of that part increases. It is to be noted further that the abdominal walls in front and at the sides are formed of soft, and more or less elastic, tissues. In health pressure is, by means of the muscles contained in these walls, exerted upon the abdominal contents, and can be therefore put upon the abdominal veins and venous capillaries. This physiological compression of the abdominal contents is rendered more powerful by the use of a waist-belt. Here, then, we have an explanation of the extensive use of some form or other of waist-belt by all nations who have passed beyond the stage of absolute barbarity.

The waist-belt is of use and has constantly been used in cases of sudden and great exertion, and in those cases where, through want of tone of the abdominal wall, it becomes necessary to counteract the tendency to a useless storing up of blood in the abdomen; and, lastly, and most frequently, by those in perfect health, by bringing more blood into the service of the brain and muscles to conduce to an increase of mental and muscular activity. Thus, for instance, is to be explained, on the first ground, the employment of tight belts by gymnasts and modern athletes. This use has been recognised from the earliest times. Thus in 2 Kings xviii. 46 (and elsewhere), where Elijah is said to 'gird up his loins,' the word for girding up is, we are informed by Professor Robertson Smith, best rendered *fortiter constrinxit*—tightly constricted. Similarly the Greek expression for an active man—*εὐζωvos*, well-girt—arose from a like conception. The Romans had a corresponding phrase, and eventually among all these nations—as among the Arabs of the present day—a loose girdle or belt when in public places was looked upon as a sign of want of vigour, and, indeed, of dissolute habits.

If the history of girdle-wearing by women be inquired into it will be found that the women of ancient Egypt, Greece, Rome, and indeed of all the more or less civilised races, employed habitually one or two, or even three, girdles placed higher up or lower down on the body (not necessarily worn simultaneously).

We are therefore brought to conclude that among women some form of waist-belt has been found advantageous. The modern corset is an article of apparel which may be said to be evolved from two separate belts—the waist-belt proper and the band over the lower ribs, the *στροφίον* of the Greeks, employed to preserve the figure. These in the course of time have become combined, and now are worn not only by the well-to-do, but by the poorest in every European country. Moderate constriction does no harm; extreme constriction is not only absurd but dangerous, inasmuch as instead of promoting exercise and activity it does the reverse, and, while causing pressure upon the veins, affects the arteries also, and disturbs the blood-supply of the abdomen and lower extremities as well. The pressure upon the abdomen should be capable of alteration according to circumstances, and should be slight after meals, when digestion is going forward and a full abdominal circulation is required.

The authors are emphatically not advocates of tight-lacing, nor is their paper written in order to urge the universal use of belts and stays. Their desire has been to point out that the widely-spread habit of wearing some form or other of waist-band, which may almost be termed an instinct, has a physiological basis, and is not of purely æsthetic origin; and, further, that there are periods at which,

within certain limits, rightly constructed abdominal bands are of use, and are not an abuse. They have not touched upon the *pathology* of abdominal constriction, this subject not being in the scope of their paper.

ZOOLOGICAL DEPARTMENT.

1. *Some Remarks on the Instincts of Solitary Wasps and Bees.*
By Sir JOHN LUBBOCK, Bart., F.R.S.

2. *Restoration of Brontops Robustus, from the Miocene of America.*
By Professor O. C. MARSH, Ph.D., LL.D.

The largest mammals of the American Miocene were the huge *Brontotheridæ*, which lived in great numbers on the eastern flanks of the Rocky Mountains, and were entombed in the fresh-water lakes of that region. They were larger than the *Dinocerata* of the Eocene, and nearly equalled in size the existing elephant. They constitute a distinct family of perissodactyles, and were more nearly allied to the rhinoceros than to any other living forms.

The deposits in which their remains are found have been called by the author the Brontotherium beds. They form a well-marked horizon at the base of the Miocene. These deposits are several hundred feet in thickness, and may be separated into different subdivisions, each marked by distinct genera or species of these gigantic mammals.

The author has made extensive explorations of these Miocene lake-basins, and has secured the remains of several hundred individuals of the *Brontotheridæ*, which will be fully described in a monograph, now well advanced towards completion, to be published by the United States Geological Survey. The atlas of sixty lithographic plates is already printed, and the author submitted a copy to the Section. The last plate of this volume is devoted to a restoration of *Brontops robustus*, one-seventh natural size, and a diagram enlarged from this plate to natural size was also exhibited.

The skeleton represented in this restoration is by far the most complete of any of the group yet discovered. It was found by the author in Dakota in 1874, and portions of it have been exhumed at different times since, some of the feet bones having been recovered during the past year. It is a typical example of the family, and shows well the characteristic features of the genus and species which it represents.

The most striking feature of the restoration here given, aside from the great size of the animal, is the skull. This is surmounted in front by a pair of massive prominences, or horn-cores, which are situated mainly on the frontal bones. The nasals contribute somewhat to their base, in front, and the maxillaries support the outer face. These elevations, or horn-cores, vary much in size and shape in the different genera and species. They are always very small in the females.

The general form of the skull and lower jaw is well shown in the figure. The prominent occipital crest, the widely expanded zygomatic arches, and the projecting angle of the lower jaw are all characteristic features. In general shape the skull resembles that of *Brontotherium*, but may be readily distinguished from it by the dental formula, which is as follows:—

Incisors $\frac{2}{1}$; canines $\frac{1}{1}$: premolars $\frac{4}{4}$; molars $\frac{3}{3}$.

The presence of four premolars in each ramus of the lower jaw is a distinctive feature in this genus. This character, with the single well-developed lower incisor, marks both the known species.

The number of teeth varies in the different genera. The form of the teeth, especially in the molar series, is more like that in *Chalicotherium* and *Diplacodon*.

than in any other known forms. The teeth in the allied genus *Brontotherium* have already been figured and described by the author.

The vertebræ are somewhat similar to those of the existing rhinoceros. In the present genus, *Brontops*, the neural spines of the dorsal vertebræ are elevated and massive. There are four sacral vertebræ in this genus, and in the known species the tail is short and slender, as in the individual here described.

The ribs are strong and massive. The sternal bones are compressed transversely. The exact form of the first one is not known with certainty, and is here restored from the rhinoceros. This is the only important point left undetermined in the restoration.

The fore limbs are especially robust. The humerus has its tuberosities and ridges very strongly developed, and the radius and ulna have their axes nearly parallel. There are four well-developed digits in the manus, the first being entirely wanting.

The pelvis is very wide, and transversely expanded, as in the elephant. The femur is long, and has the third trochanter rudimentary. The tibia and fibula are quite short. The calcaneum is very long, and the astragalus is grooved above. There are only three digits in the pes, the first and fifth having entirely disappeared.

Diplacodon of the Upper Eocene is clearly an immediate ancestor of the *Brontotheridæ*, while *Palæosyops* and *Limnohyus* of the Middle Eocene are on the more remote ancestral line. The nearest related European form is the Miocene *Chalicotherium*. No descendants of the *Brontotheridæ* are known.

Menodus, *Megacerops*, *Brontotherium*, *Symborodon*, *Menops*, *Titanops*, and *Allops* all belong to the family *Brontotheridæ*, and their relation to the genus here described, and to each other, will be fully discussed in the monograph to which reference has already been made.

3. *Heredity in Cats with an extra Number of Toes.*

By E. B. POULTON, M.A.

4. *On the Nature of the Geological Terrain as an important factor in the Geographical Distribution of Animals.* By HANS GADOW, M.A., Ph.D.

The observations concern the geographical distribution of all the species of Amphibia and Reptiles in the Iberian Peninsula, with special reference to Portugal. The number of different species amounts to 38, whilst the localities from which these species are recorded number about 800.

The method adopted—with a view of finding out a possible interdependence between geological terrain and occurrence of species—was the following: The various species and localities were arranged in five groups, which latter represent the most typical sorts of terrain in the Peninsula, viz.: Palæozoic; granite and other igneous rocks; new red sandstone; mesozoic limestones, including the cretaceous deposits; and, lastly, tertiary terrain, the latter being overlaid with sandy soil chiefly.

The proportionate areas of these five classes of terrain were given in percentage of the area of the whole country.

The most reliable conclusions could be drawn from Portugal, since this country had been extensively visited by the author on four different occasions. The following conclusions refer to Portugal only; it may, however, be especially stated that these results agree closely with those drawn from the whole peninsula. The distribution of the Reptiles exhibits features different from that of the Amphibia.

Concerning Amphibian Life.—The most favourable terrain is that of red sandstone; then follows granitic terrain, then tertiary, palæozoic, and lastly mesozoic limestone. Granitic terrain is more than six times more favourable than palæozoic, and three times more favourable than tertiary terrain. Limestone is as a rule almost detrimental. Palæozoic terrain is about seven times less favourable than red sandstone, and not half so good as tertiary terrain.

Concerning Reptilian Life.—By far the best terrain is that of red sandstone; then follows mesozoic limestone, granite, tertiary, and lastly palæozoic terrain. Granite is more than two times better than palæozoic, nearly equal to jurassic and cretaceous, and slightly better than tertiary terrain. Palæozoic terrain is many times less favourable than that of red sandstone and nearly three times worse than jurassic and cretaceous grounds.

The effect of the nature of the various sorts of terrain upon the whole flora and the healthiness of the country is remarkable.

An interesting fact is also this, that most of the snakes which frequent the sterile jurassic and palæozoic rocks are lizard-eaters, whilst the two species of *Tropidonotus* are nearly absent.

It was found that altitude, annual mean temperature, or the annual amount of rainfall by far less influence the distribution of Reptiles and Amphibia in the peninsula than the nature of the soil. High and long granitic ranges of mountains may in many cases afford no obstacle to the spreading of certain creatures, whilst other terrain, like limestone—although perhaps forming low and narrow tracts only—may act as a most effective barrier.

In conclusion, the wish is expressed that similar data, referring to other countries, may be forthcoming to enable us to verify and to correct the conclusions made in this paper. For the present they cannot be anything but suggestions, which, however, may, with more material to work with, prove capable of wider application.

5. *On the Natural History of Christmas Island.*

By J. J. LISTER, M.A., F.Z.S.

Her Majesty's surveying vessel 'Egeria' reached Christmas Island on Friday, September 30, 1887.

In the distance the sides of the island were seen to rise moderately steeply, and a shallow saddle in the middle ended in two low, rounded elevations, one of which was the summit, near the western end. On nearer approach the whole island was seen to be uniformly covered with bush, except where the bare face of a line of inland cliffs appeared. The general physical features of the island are treated of in Captain Aldrich's report.¹ The greatest length is 12 statute miles. It rises from deep sea. Soundings of over 1,000 fathoms were obtained at five points round the island, all within four miles of shore. Its volcanic origin is proved by the presence of lumps of 'compact olivine basalt and basalt tuff' at the foot of a cliff, and of a bed of 'altered volcanic stones' near the summit.² No volcanic rock was, however, found *in situ*. The surface formation of the parts of the island explored is limestone. This rock forms the summit, 1,195 feet above the sea, and covers the sides, broadening out at successive elevations into terraces which rise one above another on the sides of the island. The rock is traversed by vertical fissures which isolate tall pinnacles often 12 or 20 feet in height. The surface is weathered into irregular hollows and sharp projecting points. From the base of the lowest inland cliff a gradual slope leads to the sea, terminating in a shore cliff from 15 to 60 feet in height. This has a vertical face and is much underworn by the waves. In some places, where the sides slope less steeply into deep water, beds of live coral are seen.

The geological history of the island appears to be shortly as follows. The summit of a submarine volcanic mass has been slowly elevated above the sea to a height of nearly 1,200 feet, and, as it has passed through the zone of lime-forming organisms in shallow water, these have invested it with a cap of limestone. The upheaval has been arrested at intervals and allowed the formation of reefs which have since been elevated and form the terraces on the sides. At the projecting headlands, where the chief stress of the ocean currents fell, the reefs have grown less than in the intervals between them, and since their elevation the action of the

¹ Report on Christmas Island (Indian Ocean), H.M.S. 'Egeria.' 1887. Captain P. Aldrich, R.N.

² *Loc. cit.* p. 15.

waves has been greatest at these points; hence we find that at the headlands the terraced slopes are replaced by a single abrupt descent.

Captain Wharton points out that the raised reefs forming the summit of Christmas Island are the highest that are known in the world.

No sign of any stream was seen. The rain sinks at once into the porous limestone rock and reaches the sea by underground channels. Widely-spread littoral plants fringe the shores, *Hibiscus tileaceus*, *Tournefortia argentea*, and *Scaevola kaenigii* being abundant. Within the line of shore plants the high bush begins. Many of the trees attain 200 feet in height. Several kinds of epiphytes were found, among which a new species of *Hoya* was conspicuous.

The following vertebrate animals were observed (those marked with an asterisk are peculiar to the island):—

MAMMALS.

- **Pteropus natalis*. (Thomas.)
- A small insectivorous Bat (not obtained), *Sorex* (sp.)
- **Mus macleari*. (Thomas.)
- **Mus*, n. sp.

BIRDS

- **Merula erythropleura*. (Sharpe.)
- **Zosterops*, n. sp.
- **Collocalia*, n. sp.
- **Carpophaga whartoni*. (Sharpe.)
- **Chalcophaps*, n. sp.
- **Urospizias*, n. sp.
- **Ninox*, n. sp.
- Totanus hypoglottis*. (Linn.)
- Charadrius geoffroyi*. (Wagler.)
- Ardea jugularis*. (Forster.)
- Sula*, 2 sp.
- Fregeta aquila*. (Linn.)
- Phaethon flavirostris*. (Brandt.)
- Phaethon phoenicurus*. (Gm.)

REPTILES.

- **Gecko*, n. sp.

Snakes.

- **Typhlops exocoeti*. (Blgr.)

Turtles.

Chelonia virgata.

No Amphibia were found.

Eleven kinds of Molluscs are known, seven of which were discovered during the visit of the 'Egeria.' Five out of the eleven have been found by Mr. E. A. Smith to be peculiar to the island.

The examination of the insects has not yet been completed.

Bingus latro (Linn.)—The large land crab was very abundant.

Though the collections are, from the shortness of the visit, necessarily imperfect, the following conclusions as to the nature of the Christmas Island fauna appear to be justified.

First—Its poverty. Situated 190 miles from the nearest part of the rich Malay Archipelago, it contains, as far as is at present known, only five kinds of Mammals,

seven of land birds, four of lizards, and one snake. This seems to show that the island has been stocked by what may be called accidental means.

Secondly—Its peculiarity. Of the mammals, three out of the five are certainly peculiar, as are all the land birds, though some approach their allies on the archipelago very closely, and four out of the five reptiles. A considerable though not so high a degree of peculiarity has been found among the invertebrate forms.

Thirdly—As to the affinities. What conclusions are to be drawn as to the affinities of the fauna and flora when viewed as a whole cannot be certainly determined until the examination is complete. The birds, however, appear to be allied to those of the Austro-Malay region.

SATURDAY, SEPTEMBER 8.

The Section did not meet.

MONDAY, SEPTEMBER 10.

The following Reports and Papers were read:—

1. *Report of the Committee for aiding in the maintenance of the establishment of a Marine Biological Station at Granton, Scotland.*—See Reports, p. 319.

2. *Report of the Committee on the Development of the Oviduct in certain fresh-water Teleostei.*—See Reports, p. 338.

3. *On certain Adaptations for the Nutrition of Embryos.*
By F. W. OLIVER.

4. *On the Development of the Bulb in Laminaria bulbosa.*¹
By C. A. BARBER.

A brief description was given of a mature plant. In such a plant three parts are distinguishable. The bulb; the stalk, upon whose modifications special stress was laid; and the lamina. The bulb is merely a part of the stalk curiously altered. After a short historical summary, the development of the bulb was described in detail. It arises as a ridge upon the stalk below the lamina: this ridge grows outwards and forms a shelf-like process, which very soon curves downwards all around. A bell-shaped organ is thus formed from whose edges numerous hapteres are developed: after these hapteres have appeared, successive circles of these processes are developed in ascending order upon the expanding hollow bulb. A few points were noticed in the histology of the plant. The epidermis seems to be the only region in which active cell-division takes place. Increase in size in all parts, even at the ridge, seems to be largely dependent on increase in size of the cells. Increase in thickness is also dependent on the great thickening of the walls of the cells. This occurs especially in the elongated cells of the central strand of tissue. From these latter are sent out numerous protrusions into their thick mucilaginous walls. The protrusions thus formed penetrate in all directions, and form the so-called 'hyphal tissue.' The formation of new cells by budding seems to take place in a somewhat different form in the cortical cells of the older stalk. The epidermal cells usually appear to

¹ Published in full in *Annals of Botany*.

contain one nucleus: in other cells usually several nuclei appear: in the larger ones as many as thirty or forty may frequently be counted. In some of the inner cells of the cortex each nucleus is surrounded by a crowd of chromatophores.

There appears to be an absence of hyphal tissue in the stalk below the ridge. The cells of the hapteres are parenchymatous; they are of two kinds, larger and smaller cells alternating in such a manner that the larger cells appear to be surrounded and separated by the smaller. There is in the hapteres no strand of conducting tissue; in this respect the hapteres resemble those of Podostemaceæ. Numerous multicellular root-hairs are developed from the part of the haptere in contact with the substratum. This is due to the outgrowth of epidermal cells. The formation of sporangia takes place in exactly the same way; and these bodies occur on the inside as well as the outside of the hollow bulb.

The difference between *L. bulbosa* and allied species is seen as well in the formation of the bulb and stalk as in the position of the sporangia. The shedding of the lamina does not appear to be recorded for *L. bulbosa*.

The differentiation of the stalk is primarily due to the necessity of supporting the huge lamina. The cylindrical stalk of young specimens points to the descent of the species from a form more nearly allied to that of other Laminarias, where the stalk is still rounded. It is not easy to assign a definite reason for the departure of the stalk from its cylindrical form.

There are in this species a great amount of morphological differentiation and complicated attempts at adaptation. There does not appear to be the same amount of histological differentiation. It has not been possible to examine old specimens; but, so far as material extends, no zones of secondary thickening have been met with, neither have any mucilage-ducts been observed: the development of sieve-hyphæ is not at all well marked. Finally, the huge size of the cells and their numerous nuclei, and the increase in size by the growth of cells rather than their division, seem to point to a low stage of histological differentiation.

5. On *Pachythea*, a Silurian Alga of doubtful Affinities.¹

By C. A. BARBER.

Pachythea was described by Sir J. D. Hooker in 1853, and has, since then, received the attention of many eminent botanists. Two excellent slides have been obtained, and Sir Joseph Hooker requested the author to make drawings and descriptions for publication in the 'Annals of Botany,' offering himself to write a general historical and descriptive introduction. The historical portion was read before the Association by the permission of Sir Joseph Hooker, and the author then made a few remarks on the structure exhibited in the two slides.

There are three zones in the specimens. An outer cortical portion of radiating filaments; a central portion, consisting of a clear matrix, penetrated in different directions by filaments; and a zone of spherical bodies separating the cortex from the central part.

In the cortex the radiating filaments are divided by transverse walls; therefore the Alga does not belong to the Siphonææ. On the transverse walls are freely developed the callus-like thickenings or 'stoppers' found in *Oscillaria*, *Nostoc*, &c., and characteristic of the Floridææ. The filaments branch in a few cases, and the branching is similar to that of *Cladophora*: this removes the Alga from the group Cyanophyceæ.

In the centre the filaments are also divided by transverse walls. The stoppers and the branching have not yet been observed.

In tracing the filaments from the cortex, they usually appear to pass between the spherical bodies; and in one case they appear to arise by branching from one of the spherical bodies. In tracing the filaments from the centre, they appear to enter the spaces between the spherical bodies, and to pass between the bars which are present in these interspaces.

The large spherical bodies are of dubious nature. In one of the sections, which

¹ Published in full in *Annals of Botany*.

seems to pass through the spherical plant at some distance from its centre, there appear to be three or four rows of spherical bodies; and these are separated by well-defined interspaces of irregular form. This seems to indicate that the spherical bodies are not merely the interspaces between the radiating filaments. In the same section certain of the spherical bodies send out protrusions towards the cortex, thus becoming flask-shaped. In the other section, which appears to be cut through the centre of the plant, there is only one circle of these bodies. They have a well-defined inner wall, but appear to taper outwards towards the cortex. Between any two spherical bodies there are bars stretching across the intervening space, reminding one of the bars of *Caulerpa*, or such as are formed between the larger cells of *Furcellaria*. In one case there seems to be a connection between the spherical bodies and the radiating filaments: usually these filaments appear to pass between the spherical bodies.

Having regard to the facts mentioned, there seems to be no theory which can be accepted. More specimens must be obtained showing structure.

There are several possible explanations. The central and radiating filaments may or may not be continuous. The spherical bodies may be true cells, or they may be the interspaces between the filaments. If the central filaments are not continuous with the cortical, the former are probably parasitic. There may finally be present such a body as one of the segments of *Cymopolia*, the central part being penetrated by a parasitic alga.

6. On the Plant-remains discovered by Mr. W. M. Flinders Petrie in the Cemetery of Hawara, Lower Egypt.¹ By PERCY E. NEWBERRY.

The author called attention to the importance of this discovery to botanical science, and briefly reviewed the species of plants determined by him among the ancient remains. The condition which these plants were still in was wonderful, for, although they had lain eighteen or twenty centuries in the earth, the author had succeeded in preparing, by placing the remains in cold or warm water, a series of specimens which were as satisfactory for the purposes of science as any gathered at the present day. He had examined these plant-remains, but had been unable to detect, except in two or three instances, any peculiarities in the plants from the graves which were absent in the existing species. The author exhibited a series of specimens to illustrate his paper.

The following is a list of the ancient Egyptian plants found by Mr. W. M. Flinders Petrie in the cemetery of Hawara, Lower Egypt. Those marked with an asterisk have before been authenticated by specimens from the ancient tombs.

Nymphaea caerulea, Sav.*
Nelumbium speciosum, Willd.

7. Abnormal Ferns, Hybrids, and their Parents.¹

By E. J. LOWE, F.R.S., and COLONEL JONES.

It is not intended by anything said in this paper that the exertion of others in the same field shall be ignored; the authors only wish to record their personal experience, the labour of a number of years.

More than thirty years ago experiments were commenced, and twenty-one years ago a paper was read by Mr. Lowe, 'On Hybrid Ferns,' at the Dundee meeting of the British Association. The subject was at that time in its infancy, and none of the botanists there present, with the exception of the late Professor Balfour, thoroughly believed in these crosses. The late Mr. Clapham, who had given the subject careful investigation for some years, only became convinced by seeing a series of examples in 1879 of crosses of *Athyrium*s, in which were spores of the varieties *Victoriæ* and *Proteoides*, which series was taken to the British Association at Sheffield.

About fifteen years ago the endeavour was made to cross *Polystichum aculeatum* with *Polystichum angulare*, and when the seedlings had become mature (seven years afterwards) it was at all events apparent to one of the authors that this cross had been accomplished, but only in five examples out of a thousand seedlings. The object was to obtain a narrow cruciate variety of *Polystichum aculeatum*, a copy in *Polystichum angulare* of the narrow cruciate variety *Wakeleyanum* of *Polystichum angulare*, for as yet this was a desideratum.

Polystichum angulare, var. *Wakeleyanum*, was sown together with a dense fronded variety of *Polystichum* 'aculeatum' known as 'densum.' In 1884 specimens and a short paper were sent to the Linnean Society, but even this was not sufficient to remove the doubts of botanists; but a year later a letter from Sir Joseph Hooker stated that the crossing of ferns was then an acknowledged fact.

This hybrid, with its parents, together with the offspring of the hybrid, have been exhibited at the Bath Floral Fête amongst other specimens of botanical interest to Section D.

Colonel Jones, who is joint author with Mr. Lowe, has had (though starting a little later) great experience in the crossing of ferns, and has obtained coincident results. The instances of crossing have now accumulated to such an extent as to preclude the possibility of any further doubt on the subject.

To produce these results, however, great care is necessary that the germination of the spores should be very general and also simultaneous.

The clear proof of the reality of the crossing of varieties lies in the fact of the production of plants, either bearing a character intermediate between those of the plants sown, or combining the two characters.

A remarkable fact in connection with these crosses being the frequent transference of the character by one variety to another, this even applies to variegation. It will be seen in the example of the cruciate hybrid of *Polystichum aculeatum* that it is a marked copy of the cruciate form of *Polystichum angulare*, one of the parents selected with the object of obtaining a cruciate *Polystichum aculeatum*. Instead of the usual gradual process, the form was obtained at once. This applies

¹ This paper is to be published *in extenso* in *Annals of Botany*, with illustrations.

equally in the case of the polydactylous forms of *Polystichum angulare*, and in the variegated forms of *Scolopendrium vulgare*.

As examples there have been selected experiments made with varieties of *Athyriums*, *Scolopendriums*, and *Polystichums*. Several hundred examples might have been shown, but a few of each is ample illustration.

EXAMPLE 1.—*Athyrium*.

The following varieties were sown together: *Victoriæ*, *multifidum*, *Jonesii*, *Craigii*, *uncum*, *Harrisæ*, *cruciatum*, *Proteoides*, *tortile*, *reflexum*, *laciniatum*, and *grammicon*. The result has been several hundred intermediate forms, some very interesting.

EXAMPLE 2.—*Scolopendrium*.

In this experiment the varieties were: *Crispum* (rarely fertile), *Victoriæ*, *muriatum*, *marginatum*, *undulatum*, *digitatum*, *ramo-cristatum*, *laceratum*, and a variegated *crispum*. The result has been various intermediate forms, a number of which are variegated; for instance, the variegation in the *crispum* has passed into a crested form, the colour and not the shape being altered.

EXAMPLE 3.—*Polystichum*.

The attempt was made to so transfer the polydactylous character of certain forms of *Polystichum angulare* to other forms of *Polystichum angulare*, which, though preserving the normal outline and distinct individuality, were not polydactylous.

The forms used were Mr. Padley's polydactylous form from the vale of Avoca, and Colonel Jones's Hampshire form. The polydactylous character has now been successfully transferred to the forms known as *decompositum*, *acutilobum*, *divisilobum*, *frondosum*, *alatum*, *lineare*, *congestum*, *inæquale-variegatum*, and others. The polydactylous character of *Polystichum angulare* has also been transferred to *Polystichum aculeatum*.

There are now four clearly established cases in which the characters of distinct forms of *Polystichum angulare* have been transferred to *Polystichum aculeatum*. Hitherto the varieties of *Polystichum aculeatum* have been very few, so that now a new field for exertion is open, the results of which it is difficult to over-estimate, for the robust constitution of *Polystichum aculeatum* enables it to thrive in climates in which *Polystichum angulare* would soon perish.

The interest in the varieties of British ferns ought to increase now the crossing of varieties has become an acknowledged fact, not only on account of the extreme beauty of many of the crosses already effected, but also that, however beautiful, it may be confidently asserted that these are as nothing to what will be accomplished when exhaustive experiments, guided by tasteful and judicious selection, shall have been made. Though much will depend on such selection, there will always be enough left to the element of chance to keep up the interest.

The prospect of these endless combinations may be likened to the combinations in bell-ringing, where the changes in the ringing of twelve bells amount to 40 millions. The immense field of inquiry that can be opened up in these investigations can scarcely be conceived. The number of forms to be obtained is past all conception, and, like as the discovery of one truth is the stepping-stone to the discovery of even greater truths, so every new form that is raised enables the raiser, or those following in his footsteps, to produce countless other combinations.

8. *Preliminary Note on the Functions and Homologies of the Contractile Vacuole in Plants and Animals.* By Professor MARCUS M. HARTOG, D.Sc., M.A.

Through the practice of regarding botany and zoology as essentially distinct studies, the solution of many an interesting problem in the one domain is long missed, because the known facts that afford a clue when properly applied have

been worked out only in the other, and are contained in records never likely to be consulted in reference to the given problem. Thus, the 'contractile vacuole' is an organ that exists in both kingdoms: the question of protoplasmic vacuolation, of which this is a particular case, has only been really studied by the vegetable physiologist; and yet in the minute plant-cells which possess this organ it is too small for the study of the mechanism of its work: this study has been successfully carried out by zoologists on the larger Ciliata and Heliozoa, in ignorance, however, of the known facts that explained the reason of its working. Thus the botanists had forged a key of the right pattern, but too big to open the locks in their own domain, while fitting that of which the zoologists had described the wards and tumblers. In this preliminary publication I shall only put the key into the lock, reserving original observations for a complete paper.

I. *Distribution*.—One or more contractile vacuoles occur in all naked plant zoospores, with scarcely a recorded exception, whether mastigopod or myxopod, whether Algal, Fungal (Saprolegniæ, Peronosporæ, Chytridiæ), or Myxomycete. They occur in all fresh-water Protozoa when in the active state, though not when encysted; they are, however, absent from those that live in the perivisceral fluid or blood of living hosts from the Radiolaria, and possibly other marine forms.

II. *Position and Mechanism*.—They are vacuoles in the protoplasm, usually peripheral; they contract to disappearance at regular intervals; in favourable cases (Actinosphærium, many Ciliata) they are seen on contraction to discharge their contents into the water. In a few cases they are known to be reservoirs filled gradually by the almost continuous influx from plasmatic canals, which are invisible from this very reason, only starting into sight normally during the momentary pause when, owing to the contraction of the vacuole, their liquid contents have time to accumulate and distend them.

Now, if a specimen of sufficient size, say a Paramoecium, be placed under certain unfavourable conditions (among which is deficiency of oxygen), we find that the contractile vacuoles contract less perfectly and at longer intervals; the plasmatic canals become persistently visible and enlarged; the whole animal becomes dropsical; its thin cuticle bursts, and its protoplasm, no longer protected by the 'Hautschicht' and cuticle, and exposed directly to the water, disintegrates into 'diffuence.'

Again, if a vegetable cell be wounded in water and its protoplasm passes out, it rounds off and surrounds itself with a Hautschicht; then vacuoles appear inside; these enlarge enormously and finally burst; the protoplasm so exposed without a Hautschicht to the water disintegrates into diffuence, just like the Ciliate whose contractile vacuole works inefficiently. This pathological vacuolation and diffuence do not occur if to the water there be added a sufficiency of sugar, saltpetre, glycerine, or other innocuous osmotic substance; and when the protoplasm has the power of excreting a complete cellulose wall, as in Vaucheria, the incipient vacuolation is arrested on the formation of the wall.

The explanation of both series of facts is the same, as worked out by a series of botanists from Von Mohl to De Vries:—

Protoplasm contains in its interstices substances of high osmotic value; its outer layer at least, while freely pervious to water, is slightly if at all pervious to these substances even in solution. Hence, when protoplasm is immersed in water, cavities or vacuoles form in its substance containing solutions of these substances, which continue to enlarge by attraction of water from without; the enlargement produces a tension which De Vries and others have by various methods determined to be at least 3 atmospheres, and which may reach 15 atmospheres. Now, naked protoplasm has very little toughness, it yields readily to the increasing tension and to the expansion of the vacuole, and finally bursts and disintegrates. On the other hand, cellulose and chitinous cyst-walls are sufficiently tough to resist; and equilibrium is attained when, after a certain amount of stretching, the elasticity of the wall balances the tension of the vacuoles due to osmosis.

If, however, in the absence of a tough wall, the vacuole, instead of extending indefinitely and bursting irregularly, (a) opens by a minute pore, (b) contracts regularly as it expels its contents, (c) closes up simultaneously with the completion

of their expulsion, no part of the inner protoplasm is exposed directly to the water; and we have a mechanism which expels regularly the plasmatic juice or cell-sap when over-diluted and over-abundant, and which prevents the destruction of the protoplasm by bursting and diffuence. This is the mechanism of the contractile vacuole, which is thus a physiological necessity to the naked cell living in water like the kidney is to the multicellular animal organism.

I will add one unpublished observation to the well-known facts here brought together. Two sporanges of *Saprolegnia* opened at an early stage of the partial segregation of the protoplasm into masses. Part of the protoplasm in each slowly escaped and aggregated into rounded masses. The first discharged masses underwent the usual pathological changes and diffuence; the later masses (from both sporangia) had already acquired the power of forming contractile vacuoles possessed by the zoospores; the numerous small vacuoles appeared and contracted regularly, lines of separation formed and deepened, and the masses divided into zoospores which separated and swarmed, just like the protoplasm which remained in the sporange, though more slowly. This observation seems to afford a crucial test of the truth of the thesis that the contractile vacuole has the function of preventing excessive vacuolation and diffuence of naked cells in water.

The following is a brief summary of the points on which the above thesis rests:—

1. All naked protoplasmic bodies living in fresh water have at least one contractile vacuole.

2. The possession of this is quite independent of the systematic position of the organism.

3. The vacuole loses its contractility on the formation of a strong cell-wall or cyst and may even disappear.

4. It is absent from Gregarinida and Opalinia, and the *Radiolaria* which inhabit saline liquids.

5. When, owing to morbid conditions, the efficiency of the contractile vacuole is impaired, excessive vacuolation and diffuence ensue.

6. Conversely, as soon as contractile vacuoles appear the tendency to excessive vacuolation and diffuence is arrested.

It may be suggested that the perforations of the nephridial cells in Vermes and embryonic mollusks, and of the epiblastic gland-cells of Vermes and Arthropods, are due to the persistence of the contractile vacuole, the opening of which has become permanent, while its contractility has been superseded in the kidneys at least by other arrangements. Even the goblet-cells of mucous epithelia may possibly be traced to this origin.

9. *On the Contrivances for the Seed Protection and Distribution in Blumenbachia Hieronymi, Urban.* By W. GARDINER.

ZOOLOGICAL DEPARTMENT.

1. *On Locusts in Cyprus.* By S. BROWN.

The author gave a brief description of the habits of the common Cyprus locusts (*Stauronotus crociatus*) and of the system which has been successfully employed for their destruction in Cyprus. These insects have from time immemorial been the scourge of the island, and as, under Turkish rule, little was done to keep them down, their ravages formed probably the chief agency in reducing what was once a fertile and flourishing island to a condition of comparative desolation. Successful efforts were, however, made by the Turkish Government from 1862 to 1870 for the destruction of the locusts, and in the latter year the island was so far rid of them that for some time no injury was sustained by the crops. But the Government

relaxed its exertions and the locusts again bred and multiplied, until, by the time of the British occupation in 1878, they had so increased as to cause anxiety for the future. Acting under local advice, the Government attempted to keep them down by collecting and destroying their eggs. This operation was continued for three years on a vast scale, involving a heavy outlay, but without success, for, although this method was attempted on a scale almost without precedent, the locusts continued to increase with alarming rapidity, until in 1882 they swarmed throughout the plains, and in spite of various attempts to destroy them the damage sustained by crops was very great, and probably did not fall short of 80,000*l.*, or from 15 to 20 per cent. of the value of the crops on the infested area.

In 1883 and 1884 operations against the locusts were limited exclusively to attacking them in the crawling stage by the apparatus known as the Cyprus system of screens. These were formed of canvas and were stretched across the line of march, so that the onward progress of the locusts was arrested, and they were then diverted into pits carefully trapped, from which there was no escape. By the operations of these two years the power of the locusts was so effectually destroyed that no damage whatever has been sustained by the crops during the past five years; and although it is still necessary to watch the locusts and prevent their increase, this is now done at a comparatively small annual outlay—and their numbers have so steadily decreased year by year as to warrant the hope of their final extermination.

In submitting this paper to the Association the author was influenced by the hope that some of its members might be able to throw light on problems which (although they have received from him considerable attention) he has been unable hitherto to solve in a definite and satisfactory manner. The chief of these are:—

1. The rate of increase and the number of eggs deposited by different varieties of locusts.

2. How is it that some varieties possess the migratory instinct in an eminent degree, while others closely allied in outward form appear to be altogether devoid of it?

3. What are the laws that determine the direction of the march or flight of migratory locusts?

2. *On the Fauna of the Firth of Clyde.* By W. E. HOYLE, M.A.

3. *On a Deep-sea Tow Net.* By W. E. HOYLE, M.A.

4. *On some Points in the Natural History of the Coral Fungia.*
By J. J. LISTER, M.A., F.Z.S.

The coral fungia is abundant in shallow water on the reefs of the island of Mahé in the Seychelles Islands. Many examples of the fixed stocks were obtained. These show the disc in all stages of growth, from the young stocks with six primary septa conspicuous, to the stage in which separation of the disc takes place by absorption in a plane which is situated where the stalk is beginning to widen out into the disc.

The disc, when set free, has a scar on its under surface, exposing a section of the thecal wall, septa, trabeculæ and the soft tissues investing them. Calcareous matter is subsequently deposited over this, obliterating the scar.

A similar section is exposed on the summit of the stalk. From this a new disc is formed by growth of the septa and other structures. An early stage was obtained in which delicate fluted laminæ had been formed on the edges of the septa just projecting above the scar surface. These grow higher and higher and a new thecal wall is built up just within the margin of the thecal wall of the stalk, and thus a new disc is produced. This again is set free, when it is fully formed, at a plane above that at which the first disc was separated; and the repetition of the process gives rise to the jointed appearance of the stalk.

In many stocks the soft tissues invest the exterior of the stalk down to its base. The fully-grown discs were producing free swimming larvæ during the month of March.

5. *On the Echinodermata of the Sea of Bengal.*
By Professor F. JEFFREY BELL, M.A., Sec. R.M.S.

I am able to make an addition of some interest to the report on the Echinoderms of Ceylon which I communicated to the British Association in 1885. Collections of great interest have been made at Mergui by Dr. John Anderson, F.R.S., and at his instigation at the Andamans, while Mr. E. Thurston, Superintendent of the Madras Museum, has lately made a rather large collection at Tuticorin. If we add to the species collected at these stations those which have been noted by others, we find that the whole number of species found in the Bay of Bengal is 149. This is a considerable advance on the fifty-one specimens which, three years ago, I reported from Ceylon. The additions have not all, of course, been made since then, but the more important are due to the collections of Anderson, the Sarasins, and Thurston. If we compare the lists of forms with those given in the 'Alert Report,' we find much to support the view there held, that there is in the Indo-Pacific area an intertropical Echinoderm fauna. Within the Bay of Bengal it is not possible to show that this doctrine is erroneous, but an examination of the Persian Gulf would afford an excellent test, and it is much to be wished that such an examination might be made. It may be confidently predicted that some interesting examples of the modification of common Indo-Pacific species would be discovered therein.

TUESDAY, SEPTEMBER 11.

The following Papers and Reports were read:—

1. *Discussion on Coral Reefs.*

Mr. W. T. THISELTON-DYER, President of the Biological Section, said:—We have met this morning in conjunction with our colleagues from the Geological Section to consider a question which at the present moment is very deeply attracting the interest not merely of biologists but of geologists—the vexed question which has been raised with respect to the origin of coral islands and coral reefs. One of the earliest researches of the late Mr. Darwin was a memoir upon the origin of these islands, and in it he was disposed to attribute them in great measure to the subsidence of the land upon which they were ultimately formed. I will not anticipate the statement of the reader of the paper as to the points of difference between Mr. Darwin's views and those which are now held, but it was in consequence of the explorations of H.M.S. 'Challenger' that a series of facts were brought before the scientific world which in some degree made it extremely probable that Mr. Darwin's views did not form the only explanation to which these curious phenomena are susceptible. A very distinguished individual has thought fit to bring before the scientific world the preposterous assertion that we are leagued together in a conspiracy of silence with the object of suppressing the progress of scientific truth. I cannot pretend that that assertion has influenced us in holding this discussion to-day. It so happens that we have the presence of two distinguished scientific men who have had opportunities of examining these questions for themselves; they will state their views, and you will judge for yourselves in which direction you are inclined to think the ultimate solution of the problem may be found. At any rate I think I may claim that our minds are absolutely open, and that we attribute no weight to the authority of tradition, however eminent. The only thing we really want to know is what is the conclusion that commends itself to our minds with the greatest probability, and which is based on the largest number of ascertained facts.

Dr. SYDNEY J. HICKSON, who was then called upon to read his paper on 'Theories of Coral Reefs and Atolls,' said before commencing his paper that he held it to be the duty of the opener of a discussion such as this first of all to explain the phenomena about which discussion was to take place and then state as impartially as possible the different views held to explain the phenomena. The object of the discussion was, if possible, to arrive at the truth, and not to run any particular theory. Thus he would endeavour to state as impartially as possible the different views which had been put forward to explain the presence of atolls and barrier reefs, and, although he could not help indicating in his opening remarks the view which he was inclined to hold himself, he would endeavour to postpone the reasons for his prejudice in favour of that view to a subsequent part of the discussion. He hoped none of the gentlemen who followed him would consider that his mind was so prejudiced that they would not be able to convince him that he was wrong in the view he took. Mr. Hickson then proceeded to read his paper, the principal points in which were illustrated by maps and diagrams.

At the close of Dr. Hickson's paper the PRESIDENT said they would all agree with him that they must tender their hearty thanks to Dr. Hickson for his very admirable address. If he found any fault with it, it would be that in relation to their conference it had been of a too judicial and well-balanced character, that he had rather taken the sting out of anything like an animated controversy. They must admire the fair way in which Dr. Hickson had brought forward the arguments for and against in this controversy. It would be difficult to attack him, for he had avoided controversial matter by presenting both sides in a very fair manner. For his own part, being a botanist, and knowing very little indeed about coral islands, his mind was perfectly open in the matter. If he might venture to throw out a suggestion with regard to the arguments of future speakers, he might say he was struck with the anxiety of those who attacked Mr. Darwin's views, whilst asserting that no considerable amount of subsidence of the earth's crust had taken place, to go very largely into the correlative action, as it seemed to him, of elevation. If they admitted that portions of the earth's crust had been elevated 500 or 600 feet, it appeared to him that other portions of the earth might be correspondingly depressed. The President then invited discussion.

Professor BOYD DAWKINS said he thought they were particularly fortunate that morning in having that subject brought before the two Sections which were so closely connected as Sections C and D, for if on the one hand Section D had to deal with the history of life on the earth at the present time, Section C had to regard those changes which were revealed in the history of the earth by the study of the various forms which had lived. And the question of coral reefs might be said to stand absolutely on the frontiers which divide the province of Section C from that of Section D. He certainly felt that the Chairman had, to a very large extent, by his remarks, anticipated one of those points which certainly had, to his mind, very great force in this matter. It certainly seemed to him, as a student of the history of the earth, that it was wholly impossible for them to allow that any great movements of elevation could have taken place in a given area without acknowledging the correlative movements of depression; and when they knew that there were large portions of the Pacific and some other oceans which undoubtedly bore evidences of elevation, it seemed, in the very nature of things, that there must be some traces of subsidence. It was quite impossible for him to imagine that the one operation should go on without the other, and as a matter of fact from their geological record they must look upon the surface of the earth as being in a continual state of movement up and down, and the state of the ocean as a stable, even, and regular level. He thought the discussion would direct their attention to the rival merits of the two theories—that which was started by Mr. Darwin more than fifty years ago, and which was known as the subsidence theory; and the other theory which had been placed before them, which he might term the minus-subsidence theory. It seemed to him that the latter was not capable of being entirely ignored. As he took it, corals would live on whatever they could find to perch themselves upon and develop coral reefs within the limits of coral growth, and if the centre of the land is depressed, in the nature of things, corals

will grow more on the outside than on the inside, for the reasons advanced in the address which had opened the discussion. He failed to grasp that there was any antagonism whatever between the two views. The points raised in the opening address were, for the most part, points which had been proved over and over again by the series of observations made by Professor Agassiz and recently published. He failed to see that the minus-subsidence theory was really applicable to the formation of all coral reefs, and he observed the care with which the gentleman who had brought the subject before them that morning had stated that atolls and barrier reefs might be made without subsidence. Of course they might. And he felt sure that if Mr. Darwin were there that day he would have been amongst the first to realise that the theory which he sketched out was capable of modification by the advance of knowledge and the extension of research. Such then was the main point which occurred to him to bring before them in that discussion. He felt that he was unable to impart into it any matters of controversial interest. And he doubted whether Mr. Murray would venture to assert that there were no reefs which had been formed on the Darwinian hypothesis, and he felt sure none of his disciples would be rash enough to say that all these observations made during the last few years could be said not to modify the views held so many years ago. There was, however, one other point he would like to mention. He felt equally with Professor Hickson the difficulty of accounting for the existence of atolls by what he might call the carbonic-acid or erosion theory. So far as he understood this theory, it largely depended upon the amount of coral in the water and upon the area upon which the attack was made. In the case of atolls, so far as he knew, most of them were without any of those scourings which would allow of material being carried away in solution by the action of carbonic acid. Of course the action might go on to a considerable extent, the action was going on incessantly, so that in place of having large, thick masses of perfectly recognisable coral you find masses of limestone scarcely to be distinguished for the most part from some of those reefs.

Mr. BOURNE followed with a paper, in which he upheld the arguments of Mr. Hickson.

Dr. EVANS said he was present as a member of Section C, and not as one who had paid any particular regard to the formation of coral reefs. He came there for instruction, and he had received it, and the general result was that, whether land was rising or falling—and they as geologists knew that a see-saw action was going on in different parts of the world—they knew it was possible for these coral reefs at all events to be formed. Where there was a supply of food, there the corals would thrive, and where there was a single nucleus there would be a gradual extension in all directions. The difficulty had been to account for the ring-shape of the atolls, and there had been little brought forward that day to satisfactorily account for that phenomenon. It might be doubted whether they were able to account for the action of the carbonic acid in the water; but they had been told that all the reefs were exposed to that action. To his mind this was due to another and different cause which had not been brought before them, viz., to the rainfall in the districts in which these coral islands and atolls are situated. He thought he was right in stating that, as a rule, water more or less fresh was to be found at a certain depth in almost all the islands. That water must have come from the surface in the shape of rain. Rain falling on vegetable matter would become charged with carbonic acid and would dissolve the rock on which it fell. He thought they might fairly assume that the continual process of fresh water falling upon the coral and finding its way out into the sea in a different condition, being charged with carbonate of lime, would account for the rottenness of the centre of the islands and the formation of lagoons within them. That was an element which he thought should not be left out, and as it had not been cited in the discussion he thought it but right to bring it before them.

The CHAIRMAN said that from a botanical point of view he rather distrusted any general theory that coral islands were of no great antiquity. The botanical evidence, so far as it went, did not very strongly support Mr. Bourne's argument.

Professor SEELEY observed that, when Dr. Hickson laid before them his clear statement of the views held with regard to coral reefs, he opened with expressing

a hope that he should convert them to his own views before he had finished, and when he (Professor Seeley) turned to the end of the address he found that Dr. Hickson's own view was that he was an adherent of the views of Dr. Murray. If it was possible for the subject to have been stated in so impartial a manner as it appeared to have been by Dr. Hickson, and for Dr. Hickson to be an adherent of the views of Dr. Murray, he (Professor Seeley) would like Dr. Hickson, in his reply, to lay before them the evidence which so weighed with him as to convince him of the truth of Dr. Murray's views rather than the views of Mr. Darwin. When he remembered the circumstances under which Mr. Darwin commenced the study of coral reefs he found there was one very remarkable determining influence which gave Mr. Darwin very exceptional opportunities for forming views upon this subject. Mr. Darwin told them that he had been spending the previous autumn in North Wales, studying the processes of the upheaval and depression of the earth, and he had told them how on touching upon every shore he found records of the changes in progress all over the surface of the globe. Therefore when he came to study the problems of the distribution of life on the surface of the earth at the present time he was not attacking any problem which had previously engaged his attention, but judging whether they were true. And the conclusion he arrived at was that there was no link wanting in the evidence to unite the past methods of bringing coral reefs into existence and those which govern their distribution at the present day. The great merit, as it seemed to those who, like himself, had been occupied in expounding the views of Mr. Darwin was that as new knowledge had come before them from various researches they had learnt prophecies of the upheaval of fringing reefs which were unknown in detail to Mr. Darwin; and as Semper made known his views they learnt that there was an object of exceptional modification to the views which Mr. Darwin put forward, which were in no way antagonistic to those views but were a fitting illustration of the general truth of the views of Mr. Darwin—truth which admitted of exceptional conditions of modification where the requisite conditions were present. When these views came to be stated again, appealing to mankind, they said boldly, 'We do not regard this as a novelty or revelation, or as a new basis of science to be honoured.' And why? Because it did not do for them what Mr. Darwin's view had done—given us the method of research and connected with the past geology of the earth the phenomena of the present day. All we could see in these views were exceptional conditions of coral growth, which could be harmonised with the views which Mr. Darwin had already formulated. When the objection is raised that Mr. Darwin had not fully stated this and various facts brought before us with the view of contesting what is, perhaps, found in popular text-books as an exposition of the views of Mr. Darwin, it was very much like fighting a shadow and views which were in existence long before the views which Mr. Murray brought before them. It is stated that no coral reef is known which is more than 25 fathoms in thickness. Probably no geologist knew of any reef of more than that thickness, and he knew the conditions of the growth of coral were not favourable to extreme thickness, for it was battered up by the waves and the fragments scattered about, so that the continuity of coral growth upwards was hindered. Therefore under these and various other circumstances which come under practical observation in the study of the geological structure of our country and make us acquainted with the different distribution of coral reefs he failed to see anything in the arguments brought before them at present which would lead them to see in the new views brought forward by Mr. Murray evidence which would lead them to overthrow those given by Mr. Darwin.

Mr. HARMER observed that Professor Hickson in criticising the origin of lagoons assumed that the rim of the coral would grow more actively than the centre. Was that really the case? They could understand that the rim of the atoll would cut off supplies of food, and if there were any great differences noticeable in submerged atolls they could understand that the outside conditions of growth were more favourable than those on the inside. If, however, they had a perfectly flat table-land would there be any difference—would not the coral in the centre be able to get as much oxygen and food as that at the edge? The opponents of Mr. Darwin were ready to admit any amount of elevation, whilst they were not

ready to believe in subsidence. These opponents of Mr. Darwin's views were bound to bring forward cases in which atolls were formed in connection with cases of elevation. It was necessary for them to show that elevation had taken place in cases where atolls had been formed. The President of Section C had pointed out that elevation must be compensated for by subsidence. Was it not a fact that in a volcanic district elevation often took the form of isolated peaks on which coral work could commence, and that these would be diffused over a larger area and only affect the deep sea, so that it would not so much affect the growth of coral as the elevation which gives rise to the formation of these peaks?

Dr. MILL said they must all very much regret the absence of Mr. Murray and Dr. Guppy, the latter of whom was on his way to Christmas Island. He only desired to express on Mr. Murray's behalf the gratification which he was sure he would have felt had he been present to see how fully it was understood by the members of both Sections that his theory was not really antagonistic to Mr. Darwin's, but simply pointed out facts observed by himself and others. Mr. Murray's theory of coral islands was only part of a much wider theory which was formulated by the researches of the 'Challenger.' Mr. Murray referred more particularly to the action of life and to the action of sea-water in dissolving carbonate of lime, i.e., dead carbonate of lime. The observations of the 'Challenger' and other vessels in deep sea tended to show that in the greatest depths of oceans there was no carbonate of lime, but instead of that there was a red clay. The water, however, contained more carbonate of lime in solution than that in any other part of the oceanic area. This suggested to Mr. Murray that the organisms in falling towards the bottom had their shells gradually dissolved by their passage to the deep sea. In shallower depths the organisms fall more or less. These banks are formed more readily in shallow water. Mr. Murray supposes that the coral is not the only worker, and he prefers to call these islands organic islands. Dr. Guppy found an upheaval bed closely resembling the red clay upon which the coral was growing. One question which was really of importance was, 'Is it possible that there is sufficient carbonate of lime to supply these great coral deposits?' That matter was being tested by a series of laboratory experiments, and this research was somewhat difficult to carry out. It is being tested by means of feeding a number of hens with food containing no carbonate of lime. On testing the shells of the eggs it has been found that they have in them more carbonate of lime than they have received, which shows that other processes are able to produce carbonate of lime.

Mr. POULTON wished to know whether there was no explanation that would destroy, as a means of argument, the theory that volcanic action was necessary to areas of elevation. He noticed that no data had been given as to the relative thickness of coral. He also wanted to know whether, if these movements of the earth going up and down went on, it were not possible for an atoll to be formed and then upheaved—whether atolls might not be formed by depression and afterwards elevated. Dr. Hickson had pointed out that small atolls probably arose from small peaks and then grew outwards. Mr. Bourne had pointed out that they would grow in the direction of the currents by which food would be conveyed to them, and that they rested on very small bases. The question was whether this would be really and physically possible.

The PRESIDENT said he was afraid that the time had come when they must bring this interesting discussion to a close. They would, he thought, agree, from the speeches they had heard, that scientific men as a whole did not show any marked disposition to plead one another's views. The fact was that the condition of mind which scientific men exhibited was the best guarantee for the gradual evolution of truth. They were charged by the Duke of Argyll with having entered into a conspiracy of silence; but he appealed to those present that morning and asked them whether they could see a shadow of ground for the making of such an accusation.

Dr. HICKSON observed that as the time was so late he would endeavour to make his concluding remarks as short as possible. Mr. Poulton had asked if volcanoes were always found on areas of elevation. That question was really

rather difficult to answer. As far as they knew, volcanoes were only found on areas of elevation, but they might be found on areas of subsidence; but, as Darwin had pointed out, the evidence of the subsidence sank beneath the sea and out of sight. In regions he had investigated the land was slowly but certainly being elevated. As to the thickness of the limestone there was a very great thickness below the upraised reefs, but upon that point they required further information. Mr. Poulton had alluded to the explanation he gave about the formation of the reefs. The difficulty they had to contend with was that in addition to atolls they found coral islands without the centre lagoon. In the second place they must suppose that in some cases the reef had come to the surface as a solid rock and gradually grown outwards where the submarine peak is larger and in the submarine table-lands when the reef before it reaches the surface has the form of an atoll. Mr. Harmer had asked if it was probable that the corals would grow more rapidly and better upon the rim of a submarine table-land than in the centre. The evidence which Mr. Bourne had brought forward tended to show that where there was a rush of water corals would grow much more favourably. In the Tizard Bank and the banks in the China seas the rims were to be found covered with a luxuriant growth of coral, and in the centre there was none. Regarding Professor Seeley's remarks he (Dr. Hickson) was sorry if he did not make himself quite clear in his opening words. He did not intend to say that he hoped he should convert anyone to his views, and he believed he said distinctly that his object would be to elicit the truth, and that, although he could not help his own views being evident, he did not wish to try to convert anybody to them. He protested against Professor Seeley's suggestion that he had only given them the text-book ideas of Darwin's theory. He had carefully considered the subject from every source, and he had given what he thought a fair statement in a short time of Mr. Darwin's views. Professor Seeley also said that the new views did not seem to give the connection between the geological evidence of coral reefs and the processes actually going on. He maintained that the new views did this, whilst Darwin's views did not. Mr. Darwin most distinctly stated that coral reefs only grew on coral peaks, and here we now have examples to the contrary which are consistent with Mr. Murray's theory and not with the Darwinian. The suggestion which Dr. Evans had made respecting the action of rain-water was very valuable. In reference to the remarks made by the President of Section C, he would observe that his reason for suggesting this discussion was because Darwin's most eminent pupils would not admit that coral reefs had been formed in any other way than that suggested by Darwin. His most eminent disciple distinctly stated in his reply to Mr. Murray's views that the Darwinian theory remained true of all these atolls—in other words, that where you find an atoll and barrier reef you have *ipso facto* a proof of subsidence. It seemed to him that recent researches tended to show that the presence of the two did not form proof of subsidence. They might have been formed by subsidence, but they might also have been formed in another way. It was because Mr. Darwin's eminent pupil would not concede the point which Mr. Dawkins did that he asked for this discussion. There were two points on which Mr. Darwin was wrong, first, in supposing that all the atolls and barrier reefs were formed by subsidence and in that way only; and thus the map which he gave showing areas of elevation and depression would need modification. He did not mean to say that they would need to wipe out all the blue and substitute red, but there were certain parts marked blue which must be in future marked red. The second point was that coral reefs do not only grow upon volcanic peaks, but that they may grow upon foraminiferous shells.

3. *Contributions to the Anatomy of the Tubificidæ.*
By F. E. BEDDARD, M.A., F.Z.S.

4. *On the Flora of Madagascar.* By the Rev. R. BARON.

The London Missionary Society, in whose service the author is engaged in the island of Madagascar, encourages its missionaries, by a distinct clause in its Regulations, to take up some special study as a relaxation from the usual routine of missionary life. He has been led, for various reasons, to give a portion of his time to the study of botany, and gives this morning a brief abstract of a somewhat lengthy paper on the flora of Madagascar, which he has compiled from numerous notes and observations made during several years past.

He need not here enter into detail in regard to the size and physical structure of Madagascar. Suffice it to say that the island is nearly four times the size of England and Wales. The great mountain-chain of the country, which in its highest point reaches to about 8,500 feet, runs in a longitudinal direction probably for 700 or 800 miles, but is much nearer to the east than to the west coast. The eastern half of the island, speaking roughly, consists of crystalline schists, specially gneiss invaded by granitic and basaltic bosses and masses, with numerous recently extinct volcanoes. These schists possess all the characters of Archæan rocks, and probably are such for the most part, though it is not unlikely that they are commingled with highly metamorphosed Cambrian or other palæozoic rocks. The western half of the island seems to be composed mainly of secondary and Tertiary rocks, and chiefly those of the Jurassic, Cretaceous, and Eocene systems.

A considerable part of the island is covered by primeval forest. On the eastern side there is a forest which extends probably 800 miles from north to south almost, if not entirely, without a break, and which, according to some, is continued round the island in a complete or almost complete ring, a statement which I imagine requires verification. In the western part of the island there are undoubtedly extensive forests running in a northerly and southerly direction, but how far these are continuous is not yet known. The forest in the eastern part of the island is probably from 60 to 80 miles wide in its greatest breadth, and occupies fully two-fifths, if not one half, of the total eastern area. If we take into account the whole of the island, probably about one-eighth part of it is covered with trees.

It is grievous to relate, however, that the forests of Madagascar are being destroyed in the most ruthless and wholesale manner by the natives. Every year thousands of acres of country are cleared, the trees being burned to the ground, and that for no other purpose than to provide ashes as manure for a mere handful or two of beans or a few cobs of Indian corn. The author once came across a passage which had been cut through the forest for a long distance for no other purpose than to allow space for the dragging of a tombstone which had been quarried in the neighbourhood. To make this road no fewer than about 25,000 trees had been cut down! Again, in getting planks for building purposes from the forests, there is most extravagant waste of timber. A tree is felled, and the native woodmen, not having saws, set to work with their hatchets on each side of it until the timber is reduced to the required thickness, and thus each tree, however large, supplies but a single plank. It is truly lamentable to see how, in these and other ways, the Malagasy forests, containing, as they do, valuable timber, are being consigned to destruction.

There are now known in Madagascar about 3,440 species of flowering plants, so that it may probably be said that the great bulk of the plants found in the island has been discovered. Of these so large a proportion as four-fifths or probably more are endemic. The list below shows the number of species in the Orders most largely represented, and their percentage of the total flora.

If we include the ferns, they would stand second on the list with a percentage of 8·4.

The author has long been convinced that the flora of Madagascar may be divided into three Regions. These Regions run in a longitudinal direction, following approximately the longer axis of the island. It is proposed to call them Eastern, Central, and Western (see Map). Of the 1,977 species of plants whose localities have been determined there are—

Common to the three Regions	73
„ „ Eastern and Central	142
„ „ Western and Central	59
„ „ Eastern and Western	89

The table (exhibited) shows the Orders most largely represented and their percentage of the total flora of the respective Regions.

In this table the following facts are prominent. In the Eastern Region the two most abundantly represented Orders are Filices and Leguminosæ, but the former are in proportion to the latter as much as 5 to 2. It will be noticed that Filices do not appear in the second or third column at all, the reason being that there is not sufficient data for determining their relative position. Possibly they might occupy the third or fourth place. Neither, for the same reason, do the Gramineæ appear in the third column. In the Western Region the Leguminosæ stand at the head of the list, and this order is followed by Euphorbiaceæ, but the difference between the two is very great, the proportion being more than 5 to 1. The table shows that 24·6 per cent. of the flora of the Western Region consists of Leguminosæ. The Compositæ form only 3 per cent. of the flora. In the Central Region, on the other hand, the Compositæ stand head of the list, with a percentage of 12·2. Rubiaceæ do not appear in the column representing the Western Region at all. They, in fact, only form about 2 per cent. of the flora. The Eastern, Central, and Western Regions therefore might, if we take the most largely represented Orders into account, be fairly called the Fern Region, the Composite Region, and the Leguminous Region respectively.

That the flora of the Central Region should differ widely from the floras of the Eastern and Western Regions is accounted for by the great elevation above the sea of the central part of the island. But how are we to explain the existence of so great a difference between the floras of the Eastern and Western Regions, occupying, as they do, the same latitudinal and altitudinal positions, for of the 1,355 plants found in the Eastern and Western Regions only 89 are common to both? The explanation is believed to be simple. The central elevated plateau of the island, which runs from north to south, is undoubtedly of very great antiquity, having existed not improbably from palæozoic times, and has therefore always formed a barrier between the floras of the Eastern and Western Regions. The floras therefore, even if they were formerly similar, have had abundance of time to become differentiated in character; and if they were originally different, they have been kept, by the existence of the mountain barrier, distinct to the present day.

In another paper of a much more extensive character than the present one, the author has entered into detail in regard to the character of the three Regions. He will not, however, go into particulars here. One thing, however may be mentioned of a somewhat interesting character. In the higher portions of the Central Region there are some half-dozen plants whose distribution is remarkable. Of these one is a violet, which is also found at the height of 10,000 feet in Fernando Po and 7,000 feet in the Cameroons in West Africa, almost under the equator, and also in the mountains of Abyssinia. A geranium has a similar distribution, so have *Caucalis melanantha*, *Drosera ramentacea*, and *Lonchitis occidentalis*, which appear also on the mountains of Angola and Guinea, and *Agauria salicifolia* in Réunion, the Cameroons, and the high land about Nyassa. *Sanicula europæa* 'occurs in Central Madagascar, the mountains of Abyssinia, the Cape, 4,000–7,000 feet in the Cameroons, 4,000 feet in Fernando Po, and is widely spread through Europe and other parts of the north temperate zone.' *Cyanotis nodiflora* finds a home in Angola and Central Madagascar. These facts point plainly to the existence of a former cold (or temperate) climate within the tropics, followed by a warmer period, when these temperate plants, in order to maintain an existence, were compelled to retreat up the mountains, where they remain to the present day.

In considering the flora of Madagascar as a whole, one of the first things that strikes one is that the island must be of immense antiquity. About four-fifths of

the species and a seventh of its genera of plants are peculiar to the island. And this is as it should be; the genera have for the most part survived the untold ages that have elapsed since their first appearance, while the species have been subjected to enormous modification. Such a very large amount of specific differentiation seems to point in the clearest manner to long isolation. The antiquity of the island is also abundantly evidenced by the remarkable character of its fauna, a subject, however, which need not be discussed here. At what period the island was connected with the adjacent continent it is impossible to state with certainty, but, as has been remarked elsewhere, as nummulitic limestone occurs on a great part of the west coast of Madagascar, there seems to have been probably no land connection in Eocene times; and as the inroad of the higher forms of mammals into South Africa from the Euro-Asiatic continent probably took place, as Mr. Wallace shows, in later Miocene or early Pliocene times, Madagascar must have been cut off from the mainland at least previous to the later Pliocene period, as the absence of such mammals in the island proves.* This would allow time for the migration of the mammals to South Africa, which would not unlikely keep pace with the gradual lowering of the temperature going on in the Northern Hemisphere. This also would explain the existence of a comparatively cold period succeeded by a warm one, during which, or some part of which, Madagascar must have been joined to the mainland, for it is now well known that in the Northern Hemisphere in Tertiary time there was a gradual lowering of the temperature from that of a tropical to a temperate or even a cold climate. This being of course reversed in the Southern Hemisphere, we should have a cold period followed by a warm one. It seems probable, therefore, that Madagascar was joined to the African continent during some part or parts or the whole of the Miocene (including Oligocene) or early Pliocene period.

5. *On the Effects of the Weather of 1888 on the Animal and Vegetable Kingdoms.* By E. J. LOWE, F.R.S.

First, attention must be drawn to the extraordinary mortality amongst birds and the fearful increase in the number of slugs and insect pests during the present spring and summer near Chepstow. At Shirenewton at the present time there is not a redbreast, wren, goldcrest, coal-tit, marsh-tit, longtailed-tit, nuthatch, creeper, night jar, lesser spotted woodpecker, redcrest, grey wagtail, redstart, blackcap, white-throat, or red-pole, although usually they are all common. There are scarcely any examples of land-rail, water-ouzel, thrush, missel-thrush, dun-nock, whinchat, garden-warbler, siskin, linnet, or swallow, although these are also usually common in this district. Amongst birds those that seem to be of an average number are the crow, rook, jackdaw, magpie, jay, sparrow-hawk, swift, skylark, moor-hen, starling, and blackbird.

Usually birds are so abundant here that, without nets, cherries, strawberries, raspberries, currants, and gooseberries are all devoured by them. This year there has been no necessity for nets, as the fruit has been untouched by birds, or rather there have been no birds to eat it.

The long deep snow in February destroyed many birds, but this does not account for the absence of so many summer birds. Only four or five swallows can be seen at one time, and only a solitary land-rail has been heard.

During the last two or three weeks there has been an increase in the number of the following birds: blackbird, willow-warbler, chaffinch, sparrow, great-tit, blue-tit, spotted flycatcher, swallow, martin, and dunnoek. It may be mentioned that in June a pair of sand-grouse settled close to the cricket-ground in Shirenewton Park, but they were not seen again.

Usually there is an increase in the number of slugs and insect pests after a cold winter, and this year that increase has been enormous; seedling plants, vegetables, and flowers have been destroyed wholesale, and great damage has been done to the wheat, grass, and other agricultural crops, but what has been most noticeable is the destruction by caterpillars of all the leaves of the oak. Thousands

of oaks have been without a leaf, bare like winter, and now they are only just coming into leaf again. The damage to the oaks has extended for miles round here. Amongst destructive slugs the greatest increase has been in *Helix aspersa*, *H. rufescens*, *H. hispida*, *Zonites alliarius*, *Z. cellaria*, *Vitrina pellucida*, *Limax maximus*, *L. agrestis*, *Arion ater*, *A. empiricorum*, and *Amalia marginata*. There has also been an increase in *Testacella haliotidea* and *T. Maugei*.

Earwigs, woodlice, ants, and butterflies and beetles of numerous species have been unusually abundant, but there are no wasps and very few moles. Snakes and adders have also been numerous.

Toads and frogs deposited vast quantities of eggs, as usual, in the sheet of water in Shirenewton Park, but not a single tadpole resulted, nor did the eggs swell. The water-newt has also been much less abundant.

Early sown peas were twenty-one weeks before they were fit for the table, and all fruit has been very late, many gooseberries are not yet ripe, and currants are still abundant. Pears are scarcely swelling. Nuts are, however, an enormous crop. The hay crop has been the latest ever known, and much (September 3) has yet to be harvested.

The above, together with the great snow in February and early drought, followed by heavy continuous rains, that from May 1 to August 31 yielded here 16½ inches of water, and also the long continuance of cold weather, has made this an exceptional year so far, and a great contrast to the warm summer of 1887.

6. *The Odoriferous Apparatus of the Blaps mortisaga* (Coleoptera).

By Professor GUSTAVE GILSON.

It is well known that many insects of the *Pimelids* family give out a characteristic odour. I remarked that this odour is much stronger in the *Blaps* than in other genera of the same family, as, for instance, the *Pimelia* and the *Apis* that I had observed in Italy. I tried to discover what might be the cause of this difference, and I am now able to state that there exists a special highly developed apparatus.

This apparatus is composed of two cylinders, which unite to form, under the genital organs, a very short tube opening at the lower part of the last intersegmental space of the abdomen. Each cylinder is a sac, the walls of which are covered with a great number of whitish lobes.

This sac is a receptacle where the secretion produced by the lobes is accumulated.

This secretion is an oil in which swims a considerable number of crystalline yellow needles.

I have not yet been able to get a sufficient quantity of this substance to make a chemical analysis.

The lobes are constituted by large cells, arranged as a sort of epithelium within a bag, formed of a very thin membrane.

These lobes are by no means real glandular tubes, because each secretory cell communicates directly with the surface of the common receptacle by a tiny canal. They are simple agglomerations of unicellular glands, analogous to those we find in the inner surface of the shell of many insects, especially in the vicinity of the genital organs. Since Leydig first described this kind of cell, many writers have remarked them in various species. I may mention Claus, Nussbaum, Forel, and Schiemenz. The latter found these elements grouped in lobes rather similar to those I speak of, in certain salivary glands of bees.

However, as the descriptions are not sufficiently detailed, I made a closer examination of them in the *Blaps*, where they present several peculiarities hitherto unmentioned so far as I have been able to learn.

Each cell contains an apparatus producing the odorous oil.

This apparatus itself is made up of four distinct parts:—

1. A radiating vesicle. 2. A central ampulla. 3. An excretory canal. 4. A sheath for the canal.

The vesicle is terminated by a membrane which has a dotted appearance. It contains filaments radiating from the ampulla.

These filaments pass through the membrane and become the radiating filaments of the protoplasm.

The ampulla is but a dilatation at the end of the tube.

The tube itself has a thin wall, but a solid and elastic one, and a very narrow hole.

The sheath is a formation analogous to the vesicle; it has also a membrane and radiating filaments. It varies much in length; sometimes short, sometimes very long, and rolled up in the protoplasm.

Towards the lower part it narrows gradually, and finally it becomes one with the tube itself.

A question now arises: what is the morphological significance of these productions?

To my mind it is quite clear that the membrane of the vesicle of the ampulla and of the tube are analogous to the nuclear membrane and to other productions which arise in the cell by a condensation of the protoplasmic reticulum.

The radiating filaments are nothing but radial fibres of the reticulum, which have become more regular and stronger.

It is very interesting to compare these cells with similar elements found dispersed in the abdominal region of other insects; as, for instance, in the *Carabus catenulatus*.

Two forms of cell with canal are present.

In one set the canal is in direct contact with the protoplasm from end to end. In the other, which are of spheroidal form, the end of the canal is furnished with a radiating vesicle similar to that of the *Blaps mortisaga*.

These three forms are types of three stages of development of the unicellular gland.

In the first there is only a canal in which are inserted directly the radiating filaments of the protoplasm. In the second the protoplasm around the extremity of the canal forms a radiating vesicle, but there is no sheath. And in the third we have the sheath, which is a formation analogous to the vesicle.

The odoriferous cell of the *Blaps mortisaga* represents the most complex type of the unicellular gland and one of the most complicate forms of the living cell.

7. *Report of the Committee on Provincial Museums.*—See Reports, p. 124.

8. *The effect of various substances (chiefly members of the aromatic series of organic compounds) upon the rate of secretion and constitution of the Bile.* By W. J. COLLINS, M.D., M.S., B.Sc. (Lond.), F.R.C.S.

The paper details the results of a research undertaken at the suggestion of Dr. Lauder Brunton, being part of the larger subject of the relation between chemical constitution and physiological action. The work of other experimenters in the same field is reviewed. The methods of collecting the bile are discussed and decided in favour of the formation of temporary biliary fistulæ. This was adopted in all the experiments detailed. The animals employed were guinea-pigs. The substances experimented with were—*Benzene*, *Toluene*, *Aniline*, *Toluene Diamine*, *Benzoic Acid*, *Phenol*, *Sodic Salicylate*, *Hydroquinone*, *Resorcin*, *Pyrocatechin*, *Ethyl-Ammonium Iodide*, and *Ipecacuanha*. The collected bile, both before and after the subcutaneous injection of the drug, was analysed so far as the estimation of its water, solids, and ash in every case. *Toluene* appeared to be the most decisive cholagogue of those experimented with, both as regards rate of secretion and increase of biliary solids eliminated. Experimental trials of this drug upon man have served to corroborate this conclusion.

SECTION E.—GEOGRAPHY.

PRESIDENT OF THE SECTION—Colonel Sir C. W. WILSON, R.E., K.C.B., K.C.M.G.,
D.C.L., F.R.S., F.R.G.S.

THURSDAY, SEPTEMBER 6.

The PRESIDENT delivered the following Address :—

ON opening the present session of the Geographical Section of the British Association I cannot refrain from alluding to the last occasion, now nearly a quarter of a century ago, upon which it met in this city. The chair was then filled by one to whom I, in common with others of the younger generation of that day, must ever owe a deep debt of gratitude for many kindly words of advice and encouragement. Then, as now, popular interest centred in Africa, and Sir Roderick Murchison, on taking the chair, was accompanied by a group of distinguished African explorers. Some amongst us may remember the enthusiastic greeting accorded to Livingstone, and the heartfelt sorrow caused by the announcement that the gallant, chivalrous officer, whose name will ever live in history as the discoverer of the sources of the Nile, had been cut off in the fulness of his strength and vigour.

The African travellers of the present day have shown the same pluck, the same perseverance, the same disregard of personal risk and comfort as their predecessors. One African traveller, a distinguished officer of the German army, who hoped to have been with us, has this year been awarded the highest honour which the Royal Geographical Society can confer—its gold medal. Lieut. Wissman, who possesses all Livingstone's indomitable courage, his constancy of purpose, and his kindly feeling towards the natives, has twice crossed Africa, in its widest extent, without firing a shot in anger. He returned recently to Europe, filled, like the great English traveller, with indignation at the atrocities perpetrated by the Arabs on the blacks; and eager to find means, if such there be, of putting an end to, or at least mitigating, the unspeakable horrors of the slave trade. He is now organising an expedition which has the double object of opening up the territory in Eastern Africa that falls within the sphere of German influence, and of bearing relief to Emin Pasha. In both enterprises we may heartily wish him 'God speed!'

The light thrown upon the interior of the Dark Continent is the most striking feature of geographical exploration during the last twenty-five years; and it is really the outcome of the last eleven years, for it was only in 1877 that Mr. Stanley, by his remarkable journey, gave a new continent to the world. If Sir Roderick Murchison were now alive he would feel more than gratified at results which have been so largely due to his initiative. I propose, presently, to return to the interesting subject of Africa; but I would first draw attention to the influence which the natural features of the earth's surface have had, and are still having, in conjunction with other causes, on the trade routes and commercial relations between the West and the East, and more especially with India.

The great civilisations of high antiquity appear to have risen and expanded in four riverain districts; Chinese in the basins of the Hoang Ho and the Yang-tse-

Kiang; Hindu in those of the Indus and the Ganges; Chaldæan and Assyro-Babylonian in those of the Tigris and Euphrates; and Egyptian in that of the Nile. India is separated from China, on the one hand, by rugged, lofty mountain ranges, and the high-lying plateau of Thibet; and from Mesopotamia, on the other, by the Suleiman Mountains and the Perso-Afghan plateau. Intercommunication between these early seats of man's activity must, therefore, have been of slow growth. From Mesopotamia, on the contrary, there is easy access to the Nile basin by way of Syria and Palestine, and there are indications of traffic between these districts at a very remote period. Enquiry into the causes which first led to intercommunication and into the means by which it was effected is needless. Desire of gain, lust of power, were as much a part of human nature in the earliest ages as they are now. The former induced the pioneers of commerce to feel their way across trackless deserts, and to brave the hidden dangers of the sea; and for nearly three hundred years it led gallant men to seek a way to the wealth of India through the ice-laden seas of the Arctic region. The latter brought the great empires of Assyria and Egypt into hostile conflict, and carried Alexander to the banks of the Oxus and the Indus; and it is largely answerable for the land-hunger of European states in our own generation.

Nations rise, fall, and disappear, but commerce extends in ever-widening circles, and knows no limits. Efforts are constantly being made to discover and open up new fields of commercial activity and to connect the great centres of commerce by quicker and shorter trade routes. The earliest traffic was conducted by land; men travelled together in caravans for mutual protection, and rested where food and water were to be obtained; at the most important of these halting places cities were founded. As trade extended it became necessary to carry goods through independent tribes or countries which often insisted on retaining the transit trade in their own hands, and this led to the rise of cities at points convenient for the transfer of loads and the exchange of the commodities of one country for those of another. Generally speaking this early overland trade was co-extensive with the geographical limit of the camel. Next in order to land traffic came that by water, first on rivers, then on the sea; and cities naturally sprang up at places on the coast where the merchandise brought down the rivers in boats could, conveniently and safely, be transferred to galleys or ships suitable for coasting. After a knowledge of the monsoons had been acquired men began to trust themselves to the open sea; the ships were improved, and a system was established under which voyages were made, with great regularity, at certain seasons of the year so that advantage might be taken of the periodic winds. Increased knowledge of the globe, improvements in the art of shipbuilding, and the invention of the steam-engine have gradually led to the ocean traffic of the present day, conducted by large steamers which, regardless of wind and tide, follow the most direct course from one point to another. The trade routes of the world are subject to two great modifying influences, one physical, the other political. The inland trade of India, for instance, can only reach Central Asia and the West by way of Herat or Bamian; caravan roads across the deserts of Asia and Africa must follow lines of springs or wells; climatic conditions render all Polar routes impracticable; and the removal of a physical obstacle, by the construction of the Suez Canal, is now causing a remarkable redistribution of the channels of commerce. So too disturbance of traffic by war, or its designed destruction by conquerors; and great political changes such as the establishment of the Persian Empire, the rise of Rome, the disruption of the Roman Empire, and the advent of the Arabs to power in Western Asia, divert trade from its accustomed routes and force it into new channels, to the ruin of some cities and states and the enrichment of others. The general tendency of trade so diverted is to seek, where possible, a maritime route, for water transport is not only less costly but less liable to interruption than land transport.

India, partly from its geographical position, partly from the character of its people, has always played a passive rôle in commerce, and allowed the initiative in commercial enterprise to rest with the West. The greatest advantages have always been derived from the possession of the trade between the East and the West, and, from a

remote period, the nations of the world have contended for this rich prize. One state after another has obtained and lost the prize; England now holds it, but if she is to keep what she has obtained there must be a far closer study than there has hitherto been, of geography and terrestrial phenomena in their relation to commerce. Trade between the East and the West may be divided into three periods: the *first*, during which the limits of Oriental commerce were the eastern and south-eastern shores of the Mediterranean, closed with the foundation of Carthage about 800 B.C.; the *second*, or Mediterranean, period ended in the fifteenth century; the *third*, or Oceanic period, has lasted to the present day. In the first period there were two principal lines of traffic; the southern sea route following the coast line, and the northern land route traversing Asia in its whole extent from east to west. There are indications of communication between China and the West so early as 2698 B.C.; and in 2353 B.C. an embassy arrived in China from a country which is supposed to have been Chaldæa. There is also an early notice of caravan traffic in the company of Ishmeelites, bearing spices, and balm, and myrrh to Egypt, to whom Joseph was sold (Gen. xxxvii. 25-28.) The earliest maritime people to appreciate the value of trade between the East and West were, apparently, those living along the south coast of Arabia. Happily situated between the Persian Gulf and the Red Sea, and separated by vast deserts from the great nations of Asia, the Sabæans were free from those alternations of industry and war which are so unfavourable to commercial pursuits; for centuries they possessed the commerce of India, and they became famous for their opulence and luxury. Sabæan ships visited Ceylon and the Malabar coast, and Sabæan merchants supplied Indian goods to Mesopotamia and Syria, as well as to Egypt and Ethiopia. The ships trading to the Persian Gulf discharged their cargoes near the mouth of the Euphrates; whence the traffic passed partly by river, partly by land, to the coast towns of Syria and Palestine, and through the Syrian and Cilician gates to Mazaca (*Kaisariyeh*) and Pterium (*Boghazkeui*); from the last place Indian goods found their way to Sardis and Sinope. The ships visiting the Red Sea landed goods at Elath, at the head of the gulf of Akabah, for carriage by land to Tyre and Sidon, and on the western shores of the Red Sea for transmission to Merœ, Thebes, and Memphis. At the same time silks from China, and gems from India, were carried overland to Chaldæa and Assyria; and Bactra (*Balkh*), 'the mother of cities,' rose and flourished at the central point of the transit trade. Egypt, with no timber for shipbuilding, a distrust of all foreigners, especially when they came by sea, and a settled dislike of maritime pursuits amongst her people, long neglected the opportunities afforded by her favourable geographical position. Tyre, Sidon, and other Phœnician towns, reached by easy roads from the Euphrates and the Red Sea, and from their situation commanding the Mediterranean, became centres of distribution for Indian goods; and the Phœnicians, gradually extending their operations to the Red Sea, traded with the ports of southern Arabia, and even ventured to the shores of India. It was in this first period that the Jewish kingdom reached its widest extent. During the long wars of David's reign the Jews obtained possession of the land routes over which the rich products of India were carried to Tyre and Sidon; and Solomon did all in his power, by building Tadmor in the Wilderness (Palmyra), by improving the port of Elath, and by carrying out other great works, to protect and facilitate the transit trade from which such large profits were derived. The Jews do not appear to have been the actual carriers, but many of them no doubt, following the example of their merchant-king, engaged in commercial pursuits, and wealth poured into the kingdom so that silver was made to be as stones in Jerusalem.

In the early portion of the second period the commercial prosperity of the Phœnicians reached its culminating point. Their colonies dotted the shores of the Mediterranean, and their ships passed the 'Pillars of Hercules' to Great Britain and the western shores of Africa, and floated on the waters of the Red Sea, the Persian Gulf, and the Indian Ocean. The sea-borne trade of the known world was in their hands; wealth flowed into their cities, and in the markets of Tyre tin from Cornwall and amber from the Baltic were exposed for sale with the silks, gems, and spices of the far-distant East. The decline of Phœnicia dates from the

establishment of the Persian Empire in the sixth century B.C., and after the capture of Tyre by Alexander its commerce gradually passed into the hands of the Greeks. The Persian policy of closing the Persian Gulf to commerce forced the Indian traffic along the land routes. Babylon, which had become the emporium of Eastern trade, declined, whilst Susa and Ecbatana were enriched by the transit trade which passed through them and crossed the whole extent of the empire to the Mediterranean ports. The policy of Alexander was to secure the carrying and distribution trade of the world to the Greeks; and with this object he founded Alexandria, and intended, had he lived, to restore Babylon to her former splendour. Ptolemy, his successor in Egypt, used every means in his power to draw trade to Alexandria, and the new city soon rose to opulence and splendour. The Greek merchants obtained their Indian goods from the Arab traders whom they met in the ports of southern Arabia; they landed them at Myos Hormos and Berenice on the western shore of the Red Sea, carried them by camel across the desert, and floated them down the Nile and by canal to Alexandria, whence they were distributed to the neighbouring parts of Africa and the coasts of the Mediterranean. This trade route remained unaltered until Egypt became a Roman province. Another stream of commerce passed by way of the Persian Gulf to Seleucia on the Tigris, and thence, partly by water and partly by land, through Aleppo to Antioch and Seleucia at the mouth of the Orontes; and a third followed the ancient highway from Central Asia to the ports of the Euxine and Ægean Seas.

After the rise of Rome all trade routes were directed upon the imperial city, which became a centre of distribution for the merchandise of the East. The Greeks still monopolised the sea-borne trade; and those of Egypt, recognising the advantage of their geographical position, took the direct trade to India into their hands, and extended their voyages to Kattigara, the port of the Sinæ (Chinese), in the gulf of Tongking. Alexandria became the commercial capital of the Roman Empire, the distributing centre of the world for Indian and Asiatic goods, and a place of such wealth that one of the merchants is said to have been able to maintain an army. At the same time the old ports of Tyre, Beirût, Antioch, Ephesus, Byzantium, and Trebizonde maintained their position as *termini* of the land traffic. The extent of the intercourse between the East and the West during the Roman Empire is shown by the embassy of the Seres (Chinese) to Rome in the reign of Augustus, and by the several embassies to China, which followed that sent by Marcus Aurelius in 166 A.D., until the Arab Empire interposed; as well as by the fact that in the time of Pliny the Roman imports from Asia each year were valued at 100 million sesterces (about 800,000*l.*). Trade followed well-established routes, which remained in use, with but slight modification, till the fifteenth century. There were three principal lines of communication through Central Asia, all leading from China across the desert of Gobi. The northern ran to the north of the Thien Shan by Lake Balkash to the Jaxartes (*Syr Darya*); the central passed along the southern slopes of the Thien Shan and crossed the mountains by the Terek Pass to Samarcand and the Oxus (*Amu Darya*); and the southern passed over the Pamir and through Badakhshan to Balkh. The northern route apparently went on from the Jaxartes, through Khiva, to the Caspian, which it crossed, and then ran on to the Black Sea. Even at this early period trade filtered round the northern shores of the Caspian, and later, during the Middle Ages, there was a well-established trade route in this direction through Khiva to Novgorod and the Baltic, by which the northern countries received Indian goods. From the Oxus region, reached by the central and southern lines, there were two routes to the West. One passed through Merv, crossed the Caspian, ascended the Araxes to reach Artaxates and Trebizonde, or to descend the Phasis (*Rion*) to Poti, and then coasted the shores of the Black Sea to Byzantium. The other also passed through Merv, and, running along the northern frontier of Persia, reached the shores of the Black Sea through Artaxates, or continued on through Mesopotamia, Syria, and Asia Minor to Byzantium. The land trade from India passed through the Bamian Pass to Balkh, and through Kandahar and Herat to Merv or Sarrakhs to join the great stream of Central Asian traffic. The greater portion of the carrying trade on these long lines was in the hands of the people dwelling between the Jaxartes and the Oxus,

who had their centre at Samarcand; and these Sogdians, or Asi as they are called in the Chinese annals, fearing lest they should lose the profit on the transit trade, threw every obstacle in the way of direct communication between China and the Roman Empire. The difficulties which thus interrupted the land traffic gave an impetus to the trade by sea, and so benefited Alexandria and the cities in the Persian Gulf. The sea trade at this time was carried by way of the Persian Gulf and the Red Sea. In the first case the cargoes were landed at some port on the Euphrates or Tigris, whence the goods were carried by river and caravan up the valleys of those rivers and then through Syria to Beirût and Antioch, and through Asia Minor to Ephesus, Smyrna, Constantinople, and Samsûn. In the second case the merchandise was landed either near Suez, whence it was conveyed by caravan, canal, and river to Alexandria, and at a later date to Pelusium; or at the head of the Gulf of Akabah for transport to Syria and Palestine. The sea trade was to a great extent a coasting trade, and it appears to have been shared by the Greeks and the Arabs, and perhaps by the Chinese, whose junks were to be seen at Hira, on the Euphrates, in the fifth century.

On the disruption of the Roman Empire the Byzantines, with their capital situated on the confines of Europe and Asia, naturally became the intermediaries between the East and the West, and they retained this position until the maritime towns of Italy, France, and Spain became sufficiently strong to engage in direct trade with the Mediterranean ports to which the produce of the East found its way. Until the seventh century the Sassanians held the lines of communication by land, and they did all they could to prevent Eastern produce from being carried over any other roads than those passing through their territory or by any other hands than theirs. In the sixth century they allowed an exchange of produce between the East and the West to take place at only three points: Artaxates for goods arriving from Central Asia; Nisibis for those from Central Asia and by the Tigris route; and Callinicum (*Rakka*) for those coming by way of the Persian Gulf and the Euphrates. Justinian attempted to free Oriental commerce from its dependence on the Sassanians by opening up new trade routes. The Sogdian silk merchants passed, outside of Persian territory, round the north end of the Caspian to meet those of Byzantium on the shores of the Sea of Azov and the Black Sea; the products of India were obtained from Ethiopian traders at Adulis, on the Red Sea; and Greek navigators, taking advantage of the monsoons, sailed direct from the southern end of the Red Sea to the Malabar coast and Ceylon.

In the seventh and eighth centuries the Arabs overran the whole of Central Asia, and the carrying trade by sea and by land passed into their hands. Profound modifications were thus introduced into the commercial intercourse between the East and the West. All land traffic from the East was directed upon Baghdad, which became the distributing centre whence goods were despatched by the ancient trade routes to the West, and which almost rose to the splendour of Babylon. On the sea the Arabs regained their old reputation; they sailed direct from the Red Sea to Cape Comorin, and from Ceylon to the Malay Peninsula, and extended their voyages to Kanpu on a delta arm of the Yang-tse-Kiang; they established factories in the Indian Ocean, and, in the eighth century, were so numerous in Canton as to be able to attack and pillage that city. Their only rivals were the Chinese, whose junks visited the Euphrates and Aden, and brought silks and spices to the Malabar coast to be there exchanged for the raw material and manufactures of the West.

The Eastern produce brought by the Arabs to the ports of the Mediterranean was conveyed to Europe by the merchants of Venice, Genoa, Pisa, and other towns, who also traded to Constantinople and the Black Sea. Venice from its geographical position was well adapted to be the intermediary between the East and Central Europe, and even before the rise of Islam a large share of the carrying trade of the Mediterranean had fallen into its hands through the apathy and luxurious indolence of the Byzantines. It is unnecessary to trace the rise of Venice or discuss the impetus given by the Crusades to commercial intercourse between the East and Western Europe; it will be sufficient to note that in the first quarter of the

fifteenth century the carrying trade of the Mediterranean was wholly in the hands of the Venetians, and Venice had become the distributing centre for all Europe. Venetian fleets, well guarded by war galleys, sailed at stated times for Constantinople and the Black Sea; for Syria and Egypt; for France; for Spain and Portugal, and for Holland. From the ports in those countries, as well as from Venice herself, the products of the East were carried inland over well-defined trade routes, and cities such as Pavia, Nürnberg, and Bruges, the emporium of the Hanseatic League, rose to importance as *entrepôts* of Eastern commerce.

The victorious advance of the Turks, the fall of Constantinople, the piracy in the Mediterranean, and the termination of all intercourse with China on the decline of the Mongol dynasty in the fourteenth century, combined with other circumstances to turn men's minds towards the discovery of a more convenient way to the East. India was the dream of the fifteenth-century merchant, and how to reach it by a direct sea voyage was the problem of the day. The problem was solved when Vasco de Gama reached the shores of India on May 20, 1498; and its solution was due to the wise policy of a great-grandson of Edward III., Prince Henry of Portugal, 'the Navigator,' who unfortunately died before success was attained. The discovery of the Cape route was no mere accident, but the result of scientific training, deep study, careful preparation, and indomitable perseverance. Prince Henry having determined to find a direct sea route to India, invited the most eminent men of science to instruct a number of young men who were educated under his own eye, and in a few years he made the Portuguese the most scientific navigators in Europe. The successful voyage of Vasco de Gama soon produced important results; the saving in freight by the direct sea route was enormous, and when it became generally known that the products of the East could be obtained much cheaper in Lisbon than anywhere else, that city became the resort of traders from every part of Europe. From Lisbon Indian commodities were carried to Antwerp, which soon became the emporium of Northern Europe. By these changes the trade of Venice was almost annihilated, and Lisbon became the richest commercial city in Europe. The Venetians had endeavoured to confine commerce within its existing limits, and to keep to the trade routes then in use. They had never made any attempt to enlarge the sphere of nautical and commercial enterprise, and the consequence was that their ablest seamen, imbued with the spirit of adventure, took service in the Western States. When the Cape route was discovered, instead of attempting to secure a share in the direct sea trade, they entered into an alliance with the Sultan of Egypt to crush the Portuguese, and built a fleet for him at Suez, which was defeated by Almeida in 1508. After this defeat the trade of Venice soon passed away.

Since the discovery of the Cape route there has been one long struggle for the possession of the commerce of India; who should be the carriers and distributors of Indian commodities was for more than two and a half centuries a much contested point amongst the maritime nations of the West. At first there seems to have been a general acquiescence in the claim of the Spaniards and Portuguese to a monopoly of the southern sea-routes, and this led to those heroic efforts to find a north-east or north-west passage to India which have so greatly added to our geographical knowledge. Failure in this direction was followed by attempts to reach India by the Cape in the face of the hostile attitude of Spain and Portugal. The mighty events which in turn transferred wealth and commerce from Lisbon to Antwerp, Amsterdam, and the banks of the Thames are matter of history, and it is scarcely necessary to say that at the close of the Napoleonic wars England remained undisputed mistress of the sea, and had become not only the carrier of all ocean-borne traffic, but the distributing centre of Indian goods to the whole world. A period of keen competition for a share in the commerce of India has again commenced amongst the states of Europe, and symptoms of a coming change in the carrying and distributing trade have been increasingly apparent since Africa was separated from Asia, nearly twenty years ago, by the genius of M. de Lesseps.

The opening of the Suez Canal, by diverting trade from the Cape route to the Mediterranean, has produced and is still producing changes in the intercourse

between the East and the West which affect this country more nearly, perhaps, than any other European state. The changes have been in three directions.

First. An increasing proportion of the raw material and products of the East is carried direct to Mediterranean ports, by ships passing through the Canal, instead of coming, as it once did, to England for distribution. Thus Odessa, Trieste, Venice, and Marseilles are becoming centres of distribution for Southern and Central Europe, as Antwerp and Hamburg are for the North; and our merchants are thus losing the profits they derived from transshipping and forwarding Eastern goods to Europe. It is true that the carrying trade is still, to a very great extent, in English hands; but should this country be involved in a European war the carrying trade, unless we can efficiently protect it, will pass to others, and it will not readily return. Continental manufacturers have always been heavily handicapped by the position England has held since the commencement of the century, and the distributing trade would doubtless have passed from us in process of time. The opening of the Canal has accelerated the change, to the detriment of English manufactures, and consequently of the national wealth; and it must tend to make England less and less each year the emporium of the world. We are experiencing the results of a natural law, that a redistribution of the centres of trade must follow a rearrangement of the channels of commerce.

Second. The diversion of traffic from the Cape route has led to the construction of steamers for special trade to India and the East through the Canal. On this line coaling stations are frequent, and the seas, excepting in the Bay of Biscay, are more tranquil than on most long voyages. The result is that an inferior type of vessel, both as regards coal-stowage, speed, endurance, and seaworthiness has been built. These 'canal wallahs,' as they are sometimes called, are quite unfitted for the voyage round the Cape, and should the Canal be blocked by war or accident they would be practically useless in carrying on our Eastern trade. Since the Canal has been deepened they have improved, for it has been found cheaper to have more coal-stowage, but they are still far from being available for the long voyage round the Cape. Had the Canal not been made a large number of fine steamers would gradually have been built for the Cape route, and though the sailing ships which formerly carried the India and China trade would have held their own longer, we should by this time have had more of the class of steamer that would be invaluable to us in war time, and our trade would not have been liable, as it is now, to paralysis by the closing of the Canal.

Third. Sir William Hunter has pointed out that, since the opening of the Canal, India has entered the market as a competitor with the British workman; and that the development of that part of the empire as a manufacturing and food-exporting country will involve changes in English production which must for a time be attended by suffering and loss. Indian trade has advanced by rapid strides, the exports of merchandise have risen from an average of 57 millions for the five years preceding 1874 to 88 millions in 1884, and there has been an immense expansion in the export of bulky commodities. Wheat, which occupied an insignificant place in the list of exports, is now a great staple of Indian commerce, and the export has risen since 1873 from 1½ to 21 million hundredweight. It is almost impossible to estimate the ultimate dimensions of the wheat trade, and it is only the forerunner of other trades in which India is destined to compete keenly with English and European producers.

The position in which England has been placed by the opening of the Canal is in some respects similar to that of Venice after the discovery of the Cape route; but there is a wide difference in the spirit with which the change in the commercial routes was accepted. Venice made no attempt to use the Cape route, and did all she could to prevent others from taking advantage of it; England, though by a natural instinct she opposed the construction of the Canal, was one of the first to take advantage of it when opened, and so far as the carrying trade is concerned she has hitherto successfully competed with other countries.

It is only natural to ask what the result of the opening of the Panama Canal will be. To this it may be replied that the Canal, when completed as a maritime canal, without locks, will promote commercial intercourse between the eastern and

western coasts of America; will benefit merchants by diminishing distances and reducing insurance charges; and possibly divert the course of some of the trade between the East and the West; but it will produce no such changes as those which have followed the construction of the Suez Canal.

The increasing practice of the present day is for each maritime country to import and carry the Indian and other commodities it requires, and we must be prepared for a time when England will no longer be the emporium of Eastern commerce for Europe, or possess so large a proportion as she now does of the carrying trade. So great, however, is the genius of the English people for commercial enterprise, and so imbued are they with the spirit of adventure, that we may reasonably hope loss of trade in one direction will be compensated by the discovery of new fields of commercial activity. The problem of sea-carriage has virtually been solved by the construction of the large ocean steamers which run direct from port to port without regard to winds or currents; and the only likely improvement in this direction is an increase of speed which may possibly rise to as much as thirty knots an hour. The tendency at present is to shorten sea-routes by maritime canals; to construct canals for bringing ocean-going ships to inland centres of industry; and to utilise water carriage, wherever it may be practicable, in preference to carriage by land. For a correct determination of the lines which these shortened trade routes and great maritime canals should follow, a sound knowledge of geography and of the physical condition of the earth is necessary; and instruction in this direction should form an important feature in any educational course of commercial geography. The great problem of the future is the inland carrying trade, and one of the immediate commercial questions of the day is—who is to supply the interiors of the great continents of Asia and Africa, and other large areas not open to direct sea traffic? Whether future generations will see

‘The heavens fill with commerce, argosies of magic sails,
Pilots of the purple twilight, dropping down with costly bales,’

or some form of electric carriage on land, may be matter for speculation; but it is not altogether impossible to foresee the lines which inland trade must follow, and the places which must become centres of the distributing trade, or to map out the districts which must, under ordinary conditions, be dependent upon such centres for their supply of imported commodities. The question of supplying European goods to one portion of Central Asia has been partially solved by the remarkable voyage of Mr. Wiggins last year, and by the formation of the company of the ‘Phoenix Merchant Adventurers.’ Mr. Wiggins started from Newcastle-on-Tyne for Yeniseisk, the first large town on the Yenesei, some 2,000 miles from the mouth of that river and within a few hundred versts of the Chinese frontier. On the 9th October, 1887, he cast anchor and landed his cargo in the heart of Siberia. The exploit is one of which any man might well be proud, but in Mr. Wiggins’s case there is the additional merit that success was the result of conviction, arrived at by a strict method of induction, that the Gulf Stream passed through the Straits into the Kara Sea, and that its action, combined with that of the immense volume of water brought down by the Obi and Yenisei, would free the sea from ice and render it navigable for a portion of each year. The attempts of England to open up commercial relations with the interior of Africa have too often been marked by want, if not open contempt, of geographical knowledge, and by a great deficiency of foresight; but the competition with Germany is forcing this country to pay increased attention to African commerce, and the formation of such companies as the British East African Company, the African Lakes Company, and the Royal Niger Company is a happy omen for the future.

Another branch of the subject to which attention may be briefly directed is the fact that it is becoming increasingly evident that manufactures cannot profitably be carried on at a distance from the source of the raw material and the destination of the products. In India, for instance, where the first mill for the manufacture of cotton yarn and cloth was set up in 1854, there are now over 100 cotton and jute mills with 22,000 looms and 2,000,000 spindles; and similar changes are taking place elsewhere.

I am afraid that I have frequently travelled beyond the sphere of geography. My object has been to draw attention to the supreme importance to this country of the science of commercial geography. That science is not confined to a knowledge of the localities in which those products of the earth which have a commercial value are to be found, and of the markets in which they can be sold with the greatest profit. Its higher aims are to divine, by a combination of historical retrospect and scientific foresight, the channels through which commerce will flow in the future, and the points at which new centres of trade must arise in obedience to known laws. A precise knowledge of the form, size, and geological structure of the globe; of its physical features; of the topographical distribution of its mineral and vegetable products, and of the varied forms of animal life, including man, that it sustains; of the influence of geographical environment on man and the lower animals; and of the climatic conditions of the various regions of the earth, is absolutely essential to a successful solution of the many problems before us. If England is to maintain her commanding position in the world of commerce she must approach these problems in the spirit of Prince Henry the Navigator, and by high scientific training fit her sons to play their part like men in the coming struggle for commercial supremacy. The struggle will be keen, and victory will rest with those who have most fully realised the truth of the maxim that 'knowledge is power.'

I may add that if there is one point clearer than another in the history of commerce it is this:—that when a state cannot effectually protect its carrying trade in time of war, that trade passes from it and does not return. If England is ever found wanting in the power to defend her carrying trade, her fate will only too surely, and I might almost say justly, be that of Venice, Spain, Portugal, and Holland.

I will now ask you to turn your attention for a few moments to another subject—Africa. In 1864 Sir Roderick Murchison alluded to the great continent in the following terms: 'Looking at the most recent maps of Africa, see what enormous *lacunæ* have to be filled in, and what vast portions of it the foot of the white man has never trodden.' It was then impossible to give a general sketch even of the geography of Equatorial Africa. Tanganyika and Nyassa had been discovered, and Speke and Grant had touched at a few points on the southern, western, and northern shores of the Victoria Nyanza; but we were still in ignorance of the drainage and form of the immense tract of country between the Tanganyika Lake and the Zambesi; and the heart of Africa, through which the mighty Congo rolls, was as much unknown to us as the centre of America was to our ancestors in the middle of the sixteenth century. There are now few school-boys who could not give a fairly accurate sketch of the geography of Central Africa; and a comparison of the maps published respectively in 1864 and 1888 will show how rapidly the *lacunæ* of which Sir Roderick complained are being filled in. There is still much to be done, and it is precisely in one of the few blank spots left on our maps that the man who may well be called the Columbus of Africa has so mysteriously disappeared. The discovery of the course of the Congo by Stanley has been followed by results not unlike those which attended the discovery of America by Columbus. In the latter part of the nineteenth century Africa has become to Europe what America was in the sixteenth century. Events march more rapidly now than they did then, and the efforts of the maritime nations of Europe to secure to themselves some portion of African territory and some channel through which they can pour their products into Central Africa are rapidly changing the condition of the Dark Continent.

The roads over which the land trade of Equatorial Africa now passes from the coast to the interior are mere footpaths, described by Professor Drummond in his charming book 'Tropical Africa' as being 'never over a foot in breadth, beaten as hard as adamant, and rutted beneath the level of the forest bed by centuries of native traffic. As a rule these footpaths are marvellously direct. Like the roads of the old Romans, they run straight on through everything, ridge and mountain and valley, never shying at obstacles, nor anywhere turning aside to breathe. Yet within this general straightforwardness there is a singular eccentricity and indirectness in detail. Although the African footpath is on the whole a bee-line, no

fifty yards of it are ever straight. And the reason is not far to seek. If a stone is encountered no native will ever think of removing it. Why should he? It is easier to walk round it. The next man who comes that way will do the same. . . . Whatever the cause, it is certain that for persistent straightforwardness in the general, and utter vacillation and irresolution in the particular, the African roads are unique in engineering.' No country in the world is better supplied with paths; every village is connected with some other village, every tribe with the next tribe, and it is possible for a traveller to cross Africa without once being off a beaten track. The existence nearly everywhere of a wide coast plain with a deadly climate, and the difficulties attending land transport in a country where the usual beasts of burden, such as the camel, the ox, the horse, and the mule, cannot be utilised, will probably for many years retard the development of the land trade. On the other hand, the Congo with its wide-reaching arms, the Niger, the Nile, the Zambesi, the Shiré, and the great lakes Nyassa, Tanganyika, and the Victoria and Albert Nyanzas offer great facility for water transport, and afford easy access to the interior without traversing the pestilential plains. Already steamers ply on most of the great waterways—each year sees some improvement in this respect; and a road is in course of construction from Lake Nyassa to Tanganyika which will tend, if Arab raiders can be checked, to divert inland traffic from Zanzibar to Quilimane, and will become an important link in what must be one of the great trade routes in the future. It is possible, I believe, with our present knowledge of Africa, and by a careful study of its geographical features, to foresee the lines along which trade routes will develop themselves and the points at which centres of trade will arise; but I have already detained you too long, and will only venture to indicate Sawákin, Mombasa, Quilimane, or some point near the mouth of the Zambesi, and Delagoa Bay, as places on the east coast of Africa which, from their geographical position, must eventually become of great importance as outlets for the trade of the interior.

The future of Africa presents many difficult problems, some of which will no doubt be brought to your notice during the discussion which, I trust, will follow the reading of the African papers; and there is one especially—the best means of putting an end to slave-hunting and the slave-trade—which is now happily attracting considerable attention. It is surely not too much to hope that the nations which have been so eager to annex African soil will remember the trite saying that 'property has its duties as well as its rights,' and that one of the most pressingly important of the duties imposed upon them by their action is to control the fiends in human form who, of set purpose, have laid waste some of the fairest regions of the earth, and imposed a reign of terror throughout Equatorial Africa.

The following Papers and Report were read:—

1. *Le Canal de Panama.*¹ Par F. DE LESSEPS.

2. *Meteorological Conditions of the Red Sea.*
By Lieut.-General STRACHEY, F.R.S.

3. *Sea Temperatures in the neighbourhood of Cape Guardafui.*²
By Lieut.-General STRACHEY, F.R.S.

4. *The Salinity of the Clyde Sea Area.*³
By HUGH ROBERT MILL, D.Sc., F.R.S.E.

The observations made by the staff of the Scottish Marine Station on the Clyde sea area during the years 1886 and 1887 show that the salinity of the bottom

¹ Published in the *Proceedings of the Royal Geographical Society*, Oct. 1888.

² *Ibid.* Nov. 1888.

³ Published in *extenso* in the *Transactions of the Royal Society of Edinburgh*.

water changes comparatively little with the season, always diminishing slightly from the sea towards the head of the various lochs. The surface water also freshens close to the shore and towards the upper part of the lochs; but its salinity at any time depends largely on the actual rainfall and on the height and steepness of the surrounding mountain walls, being sometimes quite fresh and freezing in severe frosts. The saltiest surface water was almost invariably found near the Otter Spit in Loch Fyne fifty miles from the open sea; the tidal current moving from deep to shallow water carries up the salter lower layers. Wind currents produce even more striking effects. When a gale blows *down* a loch, the saltiest surface water is found at the head, even though a stream enters in the immediate neighbourhood, in the position where normally it is freshest. This is in consequence of the upwelling of salt water from beneath to replace the surface layers driven away by the wind, and fully confirms Mr. Murray's theory (suggested by temperature observations) of the circulation of water in enclosed basins. Following are the average results of from eight to fourteen observations at a few selected stations spread over two years, the density being that at 60° F. (15.56° C.).

Station	Surface	Bottom	Depth
			fathoms
Mull of Cantire	1.02536	1.02540	60
South of Arran	1.02459	1.02503	25

5. *Sea Temperatures on the Continental Shelf.*¹
By HUGH ROBERT MILL, D.Sc., F.R.S.E.

The name 'continental shelf' is applied to the shallow and gradually sloping ground from the sea-margin out to the 100-fathom line, beyond which the descent to abysmal depths is abrupt. The British Islands rest on one of the widest continental shelves in the world, and the present paper summarises observations made by the author on its western edge. The observations were carried out at the request of the Fishery Board for Scotland on board H.M.S. 'Jackal' in July and August 1887, and consisted of lines of serial temperature soundings from the north-west coast of the island of Lewis seawards to beyond the 100-fathom line. This portion of the continental shelf is terraced, and the slope varies in different places. It is broken by the long Flannan bank and the small circular bank of St. Kilda, and grooved by several deeper channels. The *form* of the curves of vertical distribution of temperature and the direction of the isotherms in the temperature sections show that the water reaching the seaward edge of the shelf from the ocean consists normally of a layer more than twenty-five fathoms deep at a uniform temperature of 56°, resting on a mass of water at a temperature of 48° or 49°. The action of waves partially mixes the two layers, and they were found separated by a zone about fifteen fathoms thick, in which the temperature changed rapidly with depth. The prevailing westerly wind and eastward tidal current produced changes in this typical arrangement of layers in exact relation with the configuration of the sea-bed. The warm layer, meeting no resistance from in-

¹ Published in *extenso* in the *Scottish Geographical Magazine*, Oct. 1888.

equalities on the bottom, flows on to the shore, and tends to accumulate there, flowing back as an undercurrent, and so giving a deeper layer of warm water or a wider zone of mixture near the land. The effect of a bank is different: the colder mass of water runs up the slope, reducing the thickness of the warm layer over the bank and maintaining a lower temperature on the other side.

The chief conclusion arrived at is that the temperature of sea-water depends little on local air-temperature, but mainly on the configuration of the sea-bottom and the direction of the currents caused by tide and wind. The observations on salinity bear out these conclusions.

6. *Perspective Maps and Common Maps.*
By ARTHUR W. CLAYDEN, M.A., F.G.S.

The author called attention to the inaccuracy essential to all maps, and to the great distortion which may occur in maps of large areas like those of continents or oceans. Notice was especially drawn to the comparative uselessness of the scale of miles usually attached to such maps. It was suggested that for elementary educational purposes such maps could be advantageously replaced by others drawn in true perspective, as a better notion would thereby be given of the true figure of the earth and the relative proportions of its chief features.

7. '*Little Russia.*' By E. DELMAR MORGAN, F.R.G.S.

The region known as 'Little Russia' has no definite landmarks; some place its centre at Kharkof, others at Poltava, but at these cities I was referred to Kief, and at Kief to Luof, or Lemberg, in Austrian Galicia, if I wished to acquaint myself with the so-called Little Russian movement. Anyone wishing to study the country thoroughly should visit all these places, make some stay in the country, and read the voluminous literature on the subject. My claim to be considered an authority rests only on a few weeks passed this summer in Kharkof, Poltava, and Kief, and short excursions in each of those provinces.

Kharkof is a rising city, a Russian Chicago, with a university, founded about eighty years ago, and a select literary circle. The prevailing feeling at Kharkof is that Moscow must be considered as the mother of Slav nationalities, however much like a stepmother she may behave. This is attributable to the large admixture of great Russians in the population and the material prosperity everywhere apparent. At Kharkof, Little Russians gradually lose their distinctive characteristics and language.

At Kharkof there is a summer theatre at which national plays are acted in the Little Russian language, every attention being paid to the exact reproduction of the dress, customs, &c., of this people. From Kharkof I made an expedition to the monastery of 'Sviatiye Gori,' the 'Holy Hills,' on the right bank of the Donets. I reached it on the anniversary of its first abbot, Arsenius, and found a great number of pilgrims assembled there from various parts of Russia. This monastery ranks next to the Pecherski Lavri of Kief in importance in southern Russia. The general appearance of the country is that of a cultivated boundless plain, with occasional mounds or kurgans rising above the surface to a height of 50 or 60 feet. These are the burial-places of the earlier nomadic inhabitants, according to recent investigations.

Poltava, my next halting-place, is situated on heights overlooking the Voraklo. Notwithstanding its dreary and somewhat dilapidated appearance it is the heart of Little Russia, and its associations carry one back to the most stirring events in the history of that nationality. I made an excursion from Poltava to Count Kochubey's estate and thence to Oposhnia, where the home industries, especially pottery, leather-dressing, &c., are important. The whole of Poltava and its neighbouring provinces are overrun by Jews, much to the injury of the inhabitants. On the way to

Sorotchnitsi, in the valley of the Psiol, I visited a Stundist, one of a sect which is likely to cause no little trouble to the Government, the measures hitherto taken against them having defeated their object.

The Little Russians are a finer race than the Great Russians; they are enterprising colonists, and the charge of laziness made against them is unfounded. Their social and political tendencies are different from those of the Great Russians. Whereas these favour communal tenure and the patriarchal family life, Little Russians are all for individualising property and severing the family tie. In earlier times their *gromada*, answering to the *Mir* of Great Russia, freely discussed local affairs. The present aristocracy of landowners is descended from the Hetmans and other officers of Cossacks who were in power at the time of the rebellion against Poland in the seventeenth century and their union with Russia, or Muscovy as it was then called.

FRIDAY, SEPTEMBER 7.

The following Papers were read :—

1. *Explorations on the Ohindwin River, Upper Burmah, in 1886-87.*¹
By Colonel WOODTHORPE, R.E.

2. *A new Route from India to Tibet.*¹ By Captain W. J. ELWES.

3. *Russian Topographical Surveys.* By E. DELMAR MORGAN, F.R.G.S.

4. *Notes on the Geography of the Region from the Nile to the Euphrates as known to the ancient Egyptians.*² By the Rev. HENRY GEORGE TOMKINS.

No route was so important in the most ancient times as the great drift-way from the Persian Gulf to the Nile mouths by way of the Orontes valley, Coele-Syria and Palestine, or of Damascus and across the Jordan. The Egyptians were the greatest of primæval geographers, and have preserved for us on a profuse scale their records. Narratives of conquest, tribute-lists, despatches and private letters, and many other memorials have come down as our materials; and none are more interesting than the *cuneiform* tablets lately found at Tel-el-Amarna in Upper Egypt.

The results of examination are not yet fully available, but we are quickly filling up the map of all the country from the Egyptian eastern frontier to the banks of Euphrates for the ages before the conquest of Joshua.

From the fortified border of the Delta three routes led eastwards and northwards across the desert. 1. From Tanis (Zoan) by Pelusium along the coast. 2. From the Wâdy Tumilat, the ancient road rediscovered by the Rev. F. W. Holland. 3. The way of the Red Sea, represented by the present Hajj road.

The Etham of the Exodus was not any *Khetam*, but the Atima of the papyri, probably the el Adâm mentioned by the Rev. Greville Chester between Pelusium

¹ Published in the *Proceedings of the Royal Geographical Society*.

² Published in extenso in the *Quarterly Statement of the Palestine Exploration Fund*.

and Daphnæ (Tahpanhes). Seti I. has given us his military route, with its fortified watering stations in the desert, to the stronghold of Kanāna south of Hebron.

A very important place, besieged and taken after the expulsion of the Hyksôs by Aahmes the founder of the XVIII. dynasty, is Sharuhēn, now Tel-esh-Sheriāh, north-west of Beersheba. It used to be thought that the Egyptian armies avoided the mountain masses of Palestine. But a careful examination of the Karnak tribute-lists leads to quite a different conclusion.

The coast route was deflected far inland by a dense and impracticable forest, haunted by brigands, between Joppa and Carmel. But the hill-country was brought under the military control of Egypt by the great kings of the eighteenth dynasty.

The names of the tribute-lists are to a great extent identical with the Biblical names in the book of Joshua, &c., and many of them occur in Assyrian annals, and the greater part may be found not greatly altered as the present local names. Askalon, Joppa, Gaza, Megiddo, were Egyptian garrisons.

The great fords of the Jordan were covered by military posts on the east side, and the great route down into Arabia was secured.

Tabor and Merom and Laish were points of note. The fords of Jordan, and the Litāny (Nazana) are mentioned, and the Nahr-el-Kelb bears its own monumental testimony to the conquerors.

The Lebanon supplied its cedar and pine timber to the Pharaohs, who had garrisons there.

Along the southern Nahr-el-Kebîr (Eleutherus) a great route led to the Orontes and its fortress Kadesh in the land of the Amorites.

The Orontes valley is full of names which we meet in Egyptian tribute-lists and narratives of campaigns, and several occur near Antioch and in the Taurus.

The northern list of Thothmes III. furnishes 230 names, besides 119 in the Palestine list.

Very careful examination now shows that at least 20 of the northern names as along the Euphrates, including Pethor (of Balaam), Karkemish, and Kirkesion, and three important fortified towns renowned in the Egyptian campaigns, Anukie (Anukas of Procopius, refortified by Justinian); Hurenkal; and Inuā (perhaps Haragla or Herakleh and Einya, both on the Euphrates).

The land of Naharina extended east and west of the Euphrates, as we learn from Egyptian texts, but in the cuneiform tablets of Tel-el-Amarna it is identified with the land of Mitāni between the Euphrates and the Khabûr river. These tablets show us that the Pharaohs Amenhotep III. and IV. (Khu-en-aten) were overlords of Assyria and Babylonia, and this agrees well with the principal places on both sides of the Euphrates being included in the tribute-list of Thothmes III. A list of Euphratean names will illustrate this, reaching from above Bir-ejik to some 100 miles below Kirkesion, including positions on the east side commanding great passages of the river. Further eastward it is not proposed to go in the present paper. But the inclusion of Damascus and other places on the great route across the Jordan near Beth-shan, and the old Hajj road towards Arabia, in the lists of Thothmes is thoroughly congruous with such substantial conquest as we have now ascertained. This was the old line of march of Kedorla'omer in the days of Abraham, and in the list of Thothmes we find the same memorials in the Ono-rapha which preserves the name of the Rephaim, and Ashtaroth where these people were smitten, and perhaps Hum is the Ham (חם), where the Zuzim were likewise smitten by the old Elamite suzerain. Now the tables had been turned, and Egypt was lord of the Euphrates.

The Egyptians, for all their appliances of easy life, were a very enterprising people, and highly trained both as conquerors and administrators, and were continually forced to supply their needs from foreign lands and to defend themselves by keeping their enemies in order.

These things help to account for the thorough knowledge which they had of the geography between their own Nile and the great river Euphrates, which we are able to ascertain by Biblical and Assyrian and classic records, and by the innumerable names still fresh on the lips of the inhabitants.

The successful studies of Mariette, de Rougé, Brugsch, de Saulcy, Maspero, Conder, and others should but stimulate us, both scholars and travellers, to more perfect methods and more exhaustive results.

5. *Remarks on Mr. Tomkins' Paper.*¹ By Major CONDER, R.E.

The questions raised have been discussed for twenty years. Mr. Tomkins' geographical discoveries in Northern Syria have added to our knowledge. The races and towns known to Egyptians enable us to carry back the history and geography of Syria to 1600 B.C. The portraits of Asiatics on the monuments enable us to distinguish the races. One of these was Semitic—as shown by the geographical names. The other was Turanian—as shown by similar information. The details of personal appearance agree with this distinction, which explains the statements of the Bible as to the population of Palestine.

The geographical position of the Kheta in various ages was discussed. In Abraham's time it was as far south as Hebron, but in 1340 B.C. only in the north. The Kheta were Tartars, as shown by physical type and names of chiefs. The influence of this Turanian population on Semites as shown by language was pointed out.

Lenormant, treating on the geographical distribution of the Turanians, says they are akin to the Akkadians. He states them to have spread all over Asia Minor. Geographical nomenclature provides one of the safest methods of tracing race.

6. *Recent Explorations East of the Jordan.*
By Captain A. M. MANTELL, R.E.

The portions of eastern Palestine which have been recently explored are three in number, viz., five hundred square miles surveyed by Major Conder, R.E., to the north-east of the Dead Sea, and two portions of 450 and 240 square miles respectively near the sea of Galilee, surveyed by Herr Schumacher. The principal points were fixed with the theodolite and a triangulation linked with that of western Palestine. Detail was filled in with the prismatic compass and altitudes of subsidiary points fixed by means of the aneroid barometer. At the same time information was collected as to the Arab tribes and their history, and ruins, dolmens, &c., were measured up and sketched. Some difficulty was experienced in ascertaining the names of places, but still more in spelling them with correct Arabic letters.

About thirty Biblical sites have been recently recovered, including Mount Peor and Bamoth Baal.

Some time was spent at Ammân, a city abounding in Roman ruins. The Muhammedan remains are less important, but include a Sassanian building which throws light on early Moslem architecture. Rabboth Ammon is now occupied by a colony of Circassians.

'Arâk el Emir and the ruined palace of Hyrcanus were also sketched and photographed. They are found to agree very well with Josephus' description. Several hundred dolmens were observed, plans and sections being taken of the best preserved; those in Moab seem to be sacrificial not sepulchral. A number of menhirs were discovered, and plans were made of several large ancient stone enclosures. The latter are often imitated at the present day on a small scale. Tombs are surrounded by circular enclosures, at which the Bedowy prays and makes his offerings.

Two groups of the stone pillars called 'Serâbit' and several disc stones were also found.

Herr Schumacher's work in the Jaulân and Haurân was executed while surveying the country for a railroad to Damascus. He has drawn up geographical gazetteers of the various districts. Through his work the ancient Kokaba has been discovered. He has also fully described some of the underground cities.

¹ Published in the *Quarterly Statement of the Palestine Exploration Fund.*

In addition to the above he has surveyed and written a pamphlet on the ancient Pella.

Herr Schumacher has examined numerous dolmens, and come to the conclusion that they are sepulchral in their origin.

A large part of eastern Palestine still remains to be surveyed ; a work which ought to be carried out at the first opportunity.

7. *Jerusalem : Nehemiah's Wall and the Royal Sepulchres.*
By GEORGE ST. CLAIR, F.G.S.

The topography of ancient Jerusalem has been difficult to make out, and the site of the sepulchres of the kings of Judah remains unknown. But the problem has been simplified by recent excavations, with which the writer has a professional acquaintance. We now for the first time know the contours of the rock and the features of hill and valley before the 80 ft. of *débris* began to accumulate.

The Akra of the Maccabees being identified, it is seen how, by the recorded filling up of the Asmonean valley, the two parts of the Lower City became joined into one *crescent*, lying with its concave side towards the Upper City, according to the description of Josephus.

The investigations of Sir Charles Warren show that the temple must be placed on the summit of Moriah, with Solomon's palace south-east of it, leaving a vacant square of 300 ft. where now we have the S.W. corner of the Haram area.

From the S.E. corner of the Haram enclosure extends the wall of Ophel, discovered by Warren, running 76 ft. to the south, then bending towards the south-west. Further, it is found that from the Gate of the Chain, in the west wall of the Haram enclosure, a causeway, with complicated structures, extends westward towards the Jaffa Gate.

Having this groundwork we may proceed to place the walls:—

The third wall, built by Agrippa, does not concern us.

As regards the second wall, it suffices for the present purpose to adopt the line of Herr Conrad Schick.

The first wall was the wall of the Upper City. On the northern side it ran from the Jaffa Gate to the Haram wall. The uncertainty has been about its southern portion. The author gives, on a diagram, the line he has been led to adopt, and then shows that it corresponds in detail with the descriptions in the Book of Nehemiah. Taking Nehemiah's night survey, then the consecutive allotments of work assigned to those who repaired the walls, and, thirdly, the points successively reached and passed by the processionists when the walls were dedicated, it is shown that every mention of a gate or a tower, the number and the order of salient and re-entering angles, and every other note of locality, exactly agree with the course of the walls as suggested.

This course, moreover, involves the least possible variation from the present line of walls, and that more in the way of addition than of deviation.

The hypothesis, commending itself as true, by corresponding minutely with Nehemiah's descriptions, by tallying exactly with other Biblical references, and by meeting all the requirements of the case, has this important practical bearing, that it indicates the site of the royal sepulchres, of the stairs of the City of David, of 'the gate between two walls,' &c., and shows incontestably that Zion was the eastern hill.

SATURDAY, SEPTEMBER 8.

The Section did not meet.

MONDAY, SEPTEMBER 10.

The following Papers were read:—

1. *Tunis since the French Protectorate.*¹
By Colonel Sir LAMBERT PLAYFAIR, K.C.M.G.

The system of government adopted is totally different to that of Algeria, which may be styled 'Colonisation de luxe.' No state assistance of any kind is given, not an immigrant has been imported, not an acre of Arab land has been confiscated, and the whole civil charges borne by France do not exceed 6,000*l.* a year.

A very short time ago the interior of the country was practically a *terra incognita*; now it is being rapidly opened out to European enterprise, and it promises soon to rival Algeria in what must always be the principal industry of North Africa, viticulture.

Commerce also has increased in a notable manner, but the beautiful and characteristic arts of the country appear to be in a state of decadence.

It is impossible to speak of Tunis and be silent regarding the most eminent Frenchman there, Cardinal Lavignerie, Archbishop of Carthage and Primate of Africa, who, by the great work he has carried out, has earned the reputation of ranking almost the highest amongst the prelates of his Church. He has now been sent by the Sovereign Pontiff to preach a crusade against the nameless horrors of the African slave trade in every capital of Europe. The Cardinal's aim is first to awaken the public conscience to the enormity of the wrong which is being daily perpetrated, and which is rapidly desolating one of the fairest portions of the earth's surface, and so to prepare the way for any remedy which His Holiness may have to suggest; and which, coming from him, might well be accepted by every Christian nation in Europe, Catholic and Protestant alike.

TUESDAY, SEPTEMBER 11.

The following Papers were read :—

1. *Photographic and Photozincographic Processes employed in the Ordnance Survey.* By Colonel J. H. BOLLAND, R.E.

2. *Note on Geographical Terminology.*¹ By H. J. MACKINDER, M.A.

3. *The River of Joseph, the Fayum and Raian Basins.*
By COPE WHITEHOUSE, M.A.

The map exhibited (scale 1 in 50,000) is the result of surveys made during 1887-8, under the immediate direction of the Egyptian Government. In conformity with instructions drawn up by Colonel Western, R.E., Director-General of Works, Messrs. Lieurnur and Beychalier, of the Public Works Department, were occupied from November, 1887, to March, 1888. The results are in entire conformity with the observations heretofore presented, and demonstrate the accuracy of the sketch-map made by Captain Surtees, and the five previous lines of levels run by Mr. Stadler and Major Shahin in the various expeditions of Mr. Cope Whitehouse. The area of the Raian Basin at the contour of 30 metres (high Nile) is 686 sq. kilom., or about 180,000 acres. Its eastern extension—the Wadi Lulu—is separated from the Gharag Basin of the Fayum by a long narrow bank of hard clay and soft conglomerate, covered with blackish sand, 1,000 to 2,000 metres in width. Another small basin, the Wadi Safir, connects with the Gharag basin at level + 26 m., and the Raian Basin connects with the same depression at + 25 m. The names of *Lulu* (the Pearl) and *Safir* (the Sapphire) have been given to these basins, in view of their future use as the gate, and preliminary reservoir, when the Wadi *Raian* (irrigation) is filled and utilised as an escape for the Nile Flood and an impounding reservoir for the season of drought. The engineering details are stated in the paper in the Engineering Section. The similarity of shape with the Lake Moeris of the Ptolemaic maps is more fully developed. The Wadi Muellah—a depression in the desert to the S.E., about 30 kilometres long and 6 kilometres wide—is separated from the Raian Basin by sandhills and rock, at a mean level of 50 m. A narrow strip, 8 kilometres long and $1\frac{1}{4}$ wide, lies about 5 metres below high Nile. The southern extremity of the valley has no connection with the Nile below + 100 m. It never, therefore, served as a channel for the Nile, but the distance is not sufficient to preclude a subterranean conduit.

The survey of the Fayum has not been completed, but it is hoped that contours will be run during the coming season around the north of the lake, and the exact height of the various ruins determined. It is now beyond cavil or dispute that the narrow passage at el-Lahun, with its dyke about 3 kilometres long and 10 metres high, is the only channel of communication at the level of high Nile between the great crevice which connects the watershed of Central Africa with the eastern Mediterranean and these depressions. The area of the Fayum at this level may be put at 2,500 square kilometres (1,000 square miles), and the Raian at 680 square kilometres (250 square miles); this surface of 3,180 square kilometres (1,250 square miles) was one vast sheet of water before the dyke at el-Lahun was established, not later than B.C. 1,400. The heavy alluvial deposits of the Fayum prove that the communication was uninterrupted for a long period within historic times. There are similar deposits in the Wadi Raian. Over 100 square miles are 70 metres (200 ft.) below the level of the Mediterranean. The basins, together or separately, are perfectly adapted to control the alternate flood and drought. The Raian basin is, however, sufficient, and the Fayum appears to have been fully reclaimed at a very early period, and again, in the Roman age, as it

¹ Published in the *Proceedings of the Royal Geographical Society*, Nov. 1888.

should be in the future. There is no question that the Arabic traditions are well founded. This is also the Pithom of the mediæval Jews and Copts, and the Auaris-Heroonpolis of Manetho and the Seventy. It is a geographical problem of great importance, whose solution has been largely facilitated by the minute and accurate topography due to these protracted and laborious researches.

4. *Mission to El-Wedj.* By Captain CONYERS SURTEES.

El-Wedj is a port on the east coast of the Red Sea, used by the Egyptian pilgrims returning from Medina. In 1887 Turkish troops occupied the fort which commands the harbour. The author of this paper, temporarily seconded to the Egyptian army, was sent by the Egyptian Government to report upon the general condition of the region. Accompanied by an Egyptian officer and Mr. Cope Whitehouse, he inspected the New Fort, the Old Hill Fort of the ninth century, the alleged gold mines, a sulphur mountain, Roman remains in the Wadi Hamz, rock-hewn inscriptions, and encampments of various tribes. Photographs were exhibited, and the strategic and commercial importance of the district discussed. The whole of Egypt in Arabia east of the Gulf of Akaba has now been formally transferred to Turkey. The author is of the opinion that there is no auriferous quartz in this neighbourhood, but that petroleum does exist, and that the valleys might be occupied by a considerable population, if proper efforts were made to encourage permanent settlements.

8. *On the general adoption of the Gregorian Calendar in relation with that of the universal hour.* By Dr. CÉS. TONDINI DE QUARENGHI.

The *Bologna Academy of Science* has, by a special memoir to all scientific bodies represented at the festivals of their centenary in June last, lately submitted to the consideration of the whole scientific world the importance and urgency of finally putting an end to a rather illusory situation, as that exemplified by the fact that the many conferences and congresses assembled for arriving at the unification of time have hardly resulted in anything more than mere aspirations and exchange of ideas.

The main difficulties opposing the realisation of that most important desideratum of science are two: the want of agreement on the starting-point for fixing the unity of time, that is, *on the initial meridian*, and the want of agreement as to the notation and subdivisions of the year—in other words, the want of agreement *on the calendar*. The question of the initial meridian belongs to Section A; here I will say a few words concerning the unification of the calendar.

Let us suppose that, in compliance with the message of the President of the United States, dated January 9 last, to the Congress of Washington, steps were actually and successfully taken to secure the execution of the resolutions of the Washington Conference; that all Powers had already subscribed to the following

¹ Published in the *Proceedings of the Royal Geographical Society*, Nov. 1888.

² *Ibid.*

article of the conference:—‘*The universal day is to be a mean solar day, is to begin for all the world at the moment of mean midnight of the initial meridian,*’ and that they should agree to begin with that midnight which is, for us, between December 31, 1888, and January 1, 1889. If this happens, but without anything having been said concerning the month and year according to which the first universal day is to be dated, will that first *universal* day be January 1, 1889? or December 20, 1888 (Orthodox Calendar)? or the 28th Rebi II., 1306 (Mahomedan Calendar)? or the 28th of Tebeth, 5649 (Jewish Calendar)? or the 30th of the 11th moon of the 25th year of the 76th sexagesimal cycle (Chinese Calendar)? If the first *would-be universal* day is all this at the same time, it will be anything but *universal*, and so poor a result, after so many more or less international congresses and conferences, as a day called universal, but belonging to calendars local, national, and quite particular, and named by them, would really suggest what a Frenchman would say: ‘*Le jeu ne valait pas la chandelle.*’

They make Russia responsible for the situation. One remark only. In 1872 the Japanese Government ordered that the Chinese Calendar should be superseded by our common Gregorian, and the difficulties which Japan had to encounter were certainly not inferior to those which Russia may advance; however the reform was carried on in Japan without the least disturbance. Now, no one single Russian would confess the impossibility for Russia to do what has been successfully done by Japan. How, then, is the behaviour of Russia to be explained? In a reply to a communication recently read to the Paris Geographical Society on the Chinese Calendar, General Tcheng-Ki-tong, the representative of China, gave us the cue of the riddle. His reply was much more an excuse for the delay of Russia than an apology for the maintenance of the Chinese Calendar. ‘The Gregorian Calendar,’ he said, ‘is far from realising the idea of what science may expect. Why, then, should we hasten to adopt a calendar which Europe will soon, in all probability, be obliged to modify?’

It is this strange current rumour concerning our calendar which offers a *pretext* to delays. Russian statesmen and scientific men know very well what to think of it; they are, moreover, fully aware that England, who had too prominent a part in determining Japan to adopt our calendar, would never have advised that Government ‘to adopt a calendar which Europe will soon, in all probability, be obliged to modify.’ But ultra-Slavophiles still use that prejudice for their purposes.

Now, I have reasons for believing that Russia is far from being unwilling that the last pretext of ultra-Slavophiles be publicly discussed, and that a strong current of opinion should loudly call for the abolition of an incorrect calendar. I received, at any rate, strong encouragements even from men of high position in Russia, and a letter, bearing from its source more than a merely private character, pointed out to me what Russia had done for the unification of the hour, thus giving me to understand that, by supporting that unification, Russia had already taken an indirect but mighty initiative in the correction of her calendar.

Before concluding, I beg to make a general remark. The unification of the calendar is only possible if urged within wise limits, that is, for purposes scientific or concerning the welfare of humanity, and in *mere scientific and international relations*. Let, then, every people be at liberty to go on using, in internal matters, their own national calendar, provided it be a correct one. Do we not use two calendars, the one lunar for our movable feasts and religious purposes, and the other solar for all other purposes? This custom indicates the line to be taken with nations attached to their calendar chiefly from religious feelings.

In concluding, if, by your kind and powerful support, you were to give in a few months to the unification of the calendar, *within the said wise limits*, a stronger impulse than the Bologna Academy of Science might be able to do in ten years, neither I nor the said academy would feel envious, but only thankful, and would sincerely rejoice in your well-deserved glory before the whole world.

SECTION F.—ECONOMIC SCIENCE AND STATISTICS.

PRESIDENT OF THE SECTION—The Right Hon. Lord BRAMWELL, LL.D., F.R.S.,
F.S.S.

THURSDAY, SEPTEMBER 6.

The President delivered the following Address:—

It gives me great pleasure to meet you here to-day as President of this Section. Forgive me if I trouble you with a purely personal reason—it is that my brother, Sir F. Bramwell, is President of this Association. That is a great distinction, of which he ought to be and is proud, and one in the enjoyment of which I am proud and glad to see him.

There is another reason, not so purely personal, though somewhat so. At a meeting of this Association nine years ago it was said—and in this Section—not that Political Economy was dead, but that it had never lived—that there never was such a science. This was an awful shock to me, who for nearly two-thirds of a century have been trying to learn something about it, and who have considered, and do consider, that there is no branch of knowledge more important than that of the truths of Political Economy. The argument attracted a good deal of notice, but for my own part I confess I never understood it. It was said that Political Economy was not an independent science, but a branch of one more extensive. It seemed to me as bad an argument as one which should say that ornithology was no science because it was only a part of natural history.

Whether Political Economy can be classed under some title comprehending it and other sciences, I know not. Perhaps 'Sociology' would do. But, whether it can or cannot, it is equally a science, equally a collection of truths relating to a particular subject which constitute the knowledge of that subject.

The truth is that Political Economy is not only a science, but a necessary science when men have formed themselves into a society. What will be the best way to add to the wealth of a society must be a subject of study by that society which will lay down rules—that is to say, make laws for the purpose—and this is Political Economy. Adam Smith was not the first Political Economist, though well called the father of those rules which now prevail. But rules for the purpose existed before him, the great objection to them being that most of them were wrong. There was a law that the dead should be buried in woollen. The object was the encouragement of sheep-breeding, and the reasons given were such as would be given nowadays in support of any proposal of protection or bounty for the agriculturist or grazier. Let us see. The most important of our industries is that which works the land. It employs great capital and much labour. If people are buried in woollen, wool will rise in price, sheep will be bred, mutton will be cheaper, and so on. So laws were made for fixing wages—laws were made against regrating and forestalling, which, as Adam Smith points out, were laws against providence and thrift—laws which would have made a criminal of Joseph, who saved in the seven abundant years, and showed himself sounder as an economist than our ancestors were.

• Then think of the usury laws. All usury was thought wrong on religious

grounds. But in Henry the Eighth's time 10 per cent. was allowed, not because that was right and 11 per cent. wicked, but because it was supposed that trade would be injured if more than that percentage could be taken for interest. The percentage has been gradually lowered till forty or fifty years ago, when sound economical reasons prevailed, the usury laws were repealed, and now any amount can be taken. Mr. Henry George, however, of whom you may have heard, thinks all usury wrong. He calls himself an economist; perhaps rightly. If he is, he is a bad one.

You cannot deny that these were economical laws because you think them wrong. There are now free-traders and fair-traders—one is right, the other wrong. I think I know which is which, but I suppose each party would call itself economical, and could only be said not to be by the other because it was not right in its notions. So also, I suppose, the homœopathists and the allopathists are both doctors, both professors of the science of medicine, though one at least is wrong, perhaps both.

It may be said that all the instances I give are instances of erroneous economy. True. The good Political Economy of those times was abstinence from legislation—the cases where people were not meddled with. Buckle said, very truly, that the good done by modern legislation was the repeal of the old. But let us see a little of the good that right opinions on Political Economy have brought about.

It has made the workman a free man. He may employ himself in any work which he can get trusted to him. He may demand any wages he thinks right, refuse to work for less, and get all he can. He is no longer, by the mischievous laws of settlement, almost confined to the parish where he was born. He may go to any part of the kingdom in search of work. He is no longer subject to punishment for joining with his fellows to better his condition. He may combine with them, and agree that they will, as a body, refuse to work unless their wages are raised or other demands complied with. His doing so is no crime, provided he does not violate the freedom and rights of others.

Then look to capital. The capitalist may employ his capital as he thinks fit—in home trade or foreign trade, in using it himself, in lending it to others. He may join with others on the ordinary terms of private partnership, or in joint stock corporate partnership, with liability limited or unlimited, as he thinks fit.

But as to the goodness of following right economical rules, I say, 'circumspice.' Look around! They have been more studied and more followed here than anywhere else. Compare this country with any other. Look at its greatness, its wealth, the comfort of its people, of all classes, as compared with other countries. I do not deny our natural advantages, our mineral wealth, our admirable situation, and, mostly, the bodily and mental condition of our people. But they would have been comparatively wasted under bad economic laws. I may be told that the United States of America beat us for wealth and general prosperity, as to which I will only say that they are cultivating only their best land. We are driven to our worst. And, further, that their best writers and reasoners support very different economic laws from those which prevail there.

I say, then, Political Economy is as old as society, and exists of necessity, and is most important; for on the goodness or badness of the rules its professors believe in to a great extent depends the happiness of society. I believe its rudiments should be taught to all, and I believe that learning them would not be difficult.

For what is it when truly understood? Man has desires and wants, and therefore a disposition to gratify them, and has also a pleasure in an active life and in attaining his objects. But he has also a desire for repose, and his power of work is limited. Bearing these things in mind, Political Economy inquires what are the best ways for man to attain these objects. It is not necessary that the student should master all the ingenious and elaborate definitions in which writers on Political Economy delight. I have in my mind a book, very clever and very profound, which I can't read. It is very subtle, but not practical, and after a few pages I get bewildered. Value, wealth, capital, labour, currency, and other things are refined on to weariness, in spite of the talent exhibited.

It is a singular thing that another most important matter is very much dealt with in a like way. One would suppose that any educated person would like to have some acquaintance with the laws of his country—certainly that Englishmen would, as they are proud of their laws, and they are responsible for them. For, if wrong, the power to alter them is with those they rule. But a similar argument is used—‘The law is so dry.’ I deny it. No doubt, if you have to learn how to serve a writ, and how many days a defendant has before he need plead, and so on, it is dry and wearisome enough. But if the study is not of the practice of the law, but of its broad, general principles, it is quite otherwise. Of the four volumes of ‘Blackstone’s Commentaries,’ three, to my mind, are most agreeable reading. These general principles should be taught as a part of ordinary education. So of Political Economy—it has been called a dismal science. I never could read ten pages of him who so called it. It has been called inhuman and unfeeling. The same epithets might as well be applied to ‘Euclid’s Elements,’ or to a treatise on baking or brewing. Indeed, much more reasonably, for Political Economy lays down those rules which will procure the greatest amount of enjoyment.

The governing precepts of Political Economy are few. In my judgment, its main one is ‘*Laissez faire*’—‘let be.’ As M. Molinara says, ‘*Notre évangile se résume en quatre mots—“Laissez faire, laissez passer.”*’ Leave everyone to seek his own happiness in his own way, provided he does not injure others. Govern as little as possible. Meddle not, interfere not, any more than you can help. Trust to each man knowing his own interest better, and pursuing it more earnestly than the law can do it for him. I believe this maxim will justify most of the rules that right economists have laid down—let your people buy in the cheapest and sell in the dearest markets. That enjoins free trade. For the trader, whether he buys at home or abroad, seeks the cheapest market. If a duty is put on the foreign article to protect the home producers, the trader is interfered with. The consumer is interfered with. The law says he shall not consume that which he can get at the lowest price—that the producers, the capitalists, and the labourers shall not employ their capital and labour as they would if left to themselves; shall not produce something they could exchange with the foreigner for something he can produce more cheaply than they; shall not buy of him, and so shall lose him as a customer, and so, not being able to employ the capital and labour on what he would take, therefore must employ it in some other way.

I say this is one of the most important precepts of Political Economy. It is plain and simple—a broad, intelligible principle; and so are all the leading truths of economic teaching.

But it is not my intention to treat further on the science generally. One subject, on which I wish to say a few words particularly, is Socialism. I once said to Mr. Newmarch, known to many of you as a most able man, ‘I am a bit of a Socialist.’ He said, ‘Yes; every right-minded man has a tendency that way.’ Our reasons were the same. It is impossible not to have a doubt or misgiving whether it is right that one man should have in an hour as many pounds sterling as another has in a year; whether one man should suffer the extreme of misery and privation, and another have every, not only necessity, but superfluity. It is a truth hard to believe; but I am satisfied that it is a truth. The great object of a society in this matter should be to make what the Americans call the largest pile—the greatest quantity to be distributed and consumed. I do not say that a more equal division than exists is not desirable, but I say that in the attempt to bring it about by law the pile will be reduced. If you gave an equal share to each, do you suppose—can anyone suppose—that each would work as hard as he does now? A man would know that the lazy and idle would indulge themselves at his expense if he worked. He would feel he had a sort of right to do the same, and he would do it. I repeat what I have said, that when men are as honest as the bees we may have Socialism or Communism—not till then. As to the argument or assertion that all men are equal and have equal rights, it is untrue, and absurdly untrue. It is equivalent to saying that all men are equally strong, equally industrious, equally clever. Why should not the more industrious man be better off than the less industrious? No reason can be given. But, if that is

true of industry, why is it not true of strength and cleverness? They are natural gifts, as well as the love of work. Natural rights are talked of. Nonsense! Natural rights may exist when man is in a state of nature. What they may be, I know not. But when man is in a social state his rights are what the law gives him; and if the law is wise it will give him all he can get. Poverty and misery shock us, but they are inevitable. They could be prevented if you could prevent weakness, and sickness, and laziness, and stupidity, and improvidence; not otherwise. To tell the weak, the lazy, and the improvident that they should not suffer for their faults and infirmities would but encourage them to indulge in those faults and infirmities. If it is said that poverty and misery may exist without fault in the sufferer, it is true. But it is but rarely that they do, and the law cannot discriminate such cases. To attempt to remedy the disparity of conditions would make the well-off poor, the poor not well off. Socialism is not good for man till man himself is better.

Not that I think that Socialism would be better even than our present state. Nothing could compensate for the loss of the pleasure and excitement of struggling for the good of ourselves and of those dear to us, unless, indeed, we could feel an equal pleasure in working for the hive. But then we should be something different from what we are.

Private charity may be useful, not in indiscriminate gifts and doles—soup kitchens, coals, flannel, and clothes given to all who apply—but in careful relief, given in no case that is not investigated and seen to be deserving of help. All charity is mischievous which is given to those who ask merely because they ask and say they are in want. In this way, by careful and discriminate charity, the man of wealth with Mr. Newmarch's socialist tendency may do good and relieve his conscience.

But besides this Socialism—the Socialism of the streets, well so called by Mr. Crofts, who gives a clear account of it—this Communism—there is a mischievous disposition abroad which is continually urging on Parliament—and Parliament is too ready in agreeing to—invasions of private liberty and of private property. It is quite certain that the number of orders we are under has vastly increased. It is very clear also that private property is not regarded with as much respect as it was. Everything that is said or written against it is listened to with favour. The land particularly is attacked. Mill's 'unearned increment' is quoted as justifying taxation, as though, when private property in land was established, it did not, as in reason it did, include all increment, earned or unearned. The legal proposition of Mr. Joshua Williams that all land in this country is held of the Crown or other lord, and so the absolute property is not in the owner, is quoted to justify taking away all property in it. My old friend would have been horrified at the ridiculous and erroneous conclusion drawn from what he said. It is quite true. But all it means is this—that if a man dies intestate and without heirs, his land escheats to the Crown or other lord; so do his horse and his watch. We are not so bad as Mr. George, who has the audacity to suggest that land should practically be taken from its owners without compensation—on this principle, that their ownership was always a wrong, and they should not be compensated for being stopped doing wrong. Is it credible? Two men have saved a competency for their old age. One has bought railway stock, another land. Both have trusted to the law. The one is to have his land taken from him because he is a wrongful owner; the other is to keep his railway stock! This is approved of by some who call for the 'nationalisation of the land.' The best thing to be said in their favour is that they attach no definite idea to the words. They don't know what they mean.

Another remarkable instance of this attack on property in land is the desire to tax what are called ground-rents. I think this is the result of want of knowing better. A man has three pieces of land of the same size, situation, value. On one he builds a house at a cost of 1,000*l.* and lives in it; on another he builds a house at a cost of 1,000*l.* and lets it at a rack rent of 65*l.*, putting the annual value of his land at 15*l.*; the third he lets to a tenant at 5*l.* a year for fifty years on the terms that the tenant lays out 1,000*l.* in building a house. He, the landowner, gives up

10% a year because he will have the house at the end of fifty. The tenant is willing to build the house and give it up at the end of fifty years, because for those fifty years he will have land for 5% a year which is worth 15%. Can any human being give a reason why any one of these three houses, or their owners and occupiers in respect of them, should pay more taxes or rates than any other of them?

Then we have the enfranchisement of leaseholds. As you are to have a paper read on this, I will say no more than that you do not compensate a man when you take from him what he would rather keep as a matter of business than have what you give him—not if it is twenty shillings for his sovereign.

I regret to say that these schemes and ideas receive encouragement from Parliament. I was told by a gentleman, than whom there is no better authority, when the Manchester Ship Canal Company was unable to raise capital, that it was owing to the distrust that existed among capitalists that their property was not safe—a distrust, I regret to say, well justified. The water companies of London were entitled to charge according to the real annual value of the houses supplied. An Act was passed at the instance of a private member that the charge should be on the rated value, which is very commonly five-sixths of the real value. It was passed by some who knew no better, by others who did, not without a blush; but it was 9,000% a year loss to one company. In this last Session the following was done. If the railway companies do not make a tariff of maximum charges satisfactory to the Board of Trade, that Board may make one. In the Government Bill it was provided that their tariff should be ‘just and reasonable.’ It was objected that they might think something less than their right by statute would be just and reasonable. So it was suggested that these words should be added, ‘equivalent to their existing rates.’ This was adopted. I need say nothing more in its favour than that Lord Selbourne approved it. This was in the Lords. The Commons struck out the words ‘equivalent to their existing rates.’ The Lords acquiesced. The ever-ready Marquis gave as a reason or excuse or answer that Parliament would not adopt the new rates unless they were equivalent. But why did the Commons object to the words except to provide a power to alter the rates to what will not be equivalent?

I say property and freedom of action are not held in the respect they were and ought to be. It is to combat this that the Liberty and Property League has been established, and has struggled under their able Chairman and their indefatigable Secretary.

The following specimens of proposed interference with property and freedom of contract may interest you:—A Bill to give everyone a right of access to mountain or uncultivated moorland for recreation or study. A Bill that, notwithstanding any agreement to the contrary, a tenant may obtain compensation for *improvements* done against the landlord's consent. A Bill to compel an employer to give his servants holidays without deduction from wages. Another Bill to let a tenant *improve* without and against his landlord's consent and opinion, and against their agreement. A Bill that a colliery tenant may, *notwithstanding any agreement to the contrary*, have his lease extended if he has been unable to work owing to depressed state of trade. A Bill that everybody may fish in rivers which are highways or along which there is a right of passage. A Bill that property may be taken for labourers' dwellings without payment of compensation for loss of trade, profits, goodwill, &c. Another similar Bill, but one year's profits allowed. A Bill which may shortly be described as one to introduce into Scotland the mischief of the Irish Land Acts. A Bill that lessees of mines in Cornwall, *notwithstanding any agreement to the contrary*, may remove buildings. A Bill giving general right in Wales and Monmouth to go on lands for recreation, winberry gathering, scientific inquiry, sketching, or antiquarian research. A Bill that in every execution against the goods of a household necessary furniture to the value of 20% shall be exempt. In these cases rights of property and freedom of contract are violated.

Just one word as to Protection and Fair Trade. I have said of ‘Fair Trade’ that it is a taking phrase; but really it is unmeaning. Does a foreign nation tax our goods for the sake of revenue? What is there unfair in that? Does it do so

because it is unwise enough to believe in protection? Again, what is there unfair in that? Is it unfair to sell to us and not buy? Why? There is no deception. We will not buy of you; we do not compel you to sell to us. If you do, it is because it suits you. But let us drop the words and look at the substance. If, by not buying of the foreigner, we could make him buy of us, there might be some reason in our refusal to buy. When a case of that sort is shown it will be worth considering. Till then, if we buy of those who will not buy of us, it is because it suits us, as they say. Why? Because we get the thing we want when otherwise we should go without or get it dearer. Remember, we must pay for it; and to pay for it we must produce something else, which it is worth our while to make, and change for it—I do not mean change specifically. We deal with the world. From parts we get gold and silver. With them, with goods, with what is owing to us, we pay those who do and those who do not buy of us. A friend said: ‘Dear me, our imports are 350,000,000%, our exports only 230,000,000%,’ or whatever was the figure. I said, ‘I wish we could get them for less.’ Is protection to be argued over again? There is not a reason that can be given for it that would not be equally good for protecting tariffs between London and Southwark.

There is one more particular subject I wish to speak on. It is certain that the wonderful labour-saving inventions of modern times have diminished the manual labour required by society. If the food, clothing, and habitations of mankind are got and constructed with less labour, fewer labourers are required. Of course, I know the well-recognised truth that man’s wants and wishes are never more than supplied. But everything in this world is relative, and, though every one might like more than he has, yet his wants diminish as his havings increase. Happily, one good result of this saving of labour has been a diminution of the hours of work, an increase of leisure, one of the good things desired by mankind. But there is always a risk that, if work does not increase and workmen do, the competition among them will diminish their rewards. Another thing to be remembered is that our mineral wealth—certainly our coal—is diminishing. Further, that foreign competition increases; we have taught others how to rival us. I do not prophesy our decadence; I have the greatest confidence in my countrymen. But I do think there are considerations which should make us rejoice if our population did not increase as fast as it has done. I am glad to think that the rate of increase in the last few years has not been as great as it was formerly. No doubt a great increase of population is in one sense a cause of rejoicing. It shows a prosperous condition of things, and adds to the strength of the State. But it inevitably *tends* to a lowering of wages and a lowering of the standard of comfort in the labouring classes. It may be, and in this country has been, counteracted by other circumstances, but there is that tendency. I never sympathise with the exultation at our increase in population compared with the French. I think it very doubtful if they do not show more foresight and thrift than do our people. It is sad to see the improvident marriages of boys and girls without a shilling, or a chair or table. Of course, it is a charming thing for a man after his work to go to his home, find his comfort has been cared for by an affectionate wife, and have his children to play with, and I believe that such a man is more likely to keep out of mischief and out of the public-house; the attraction there is less, and he feels his responsibility for those dear to him. But the home should be a comfortable one for him, and this it will not be in the case of the improvident marriages I mention. I do sincerely think that they are earnestly to be deprecated, especially at the present time, and I am glad to think they are diminishing.

I will not trouble you further. I daresay there are many among you who do not share my love for Political Economy. I have endeavoured not to weary you, but to place before you some leading principles and considerations. I believe and repeat that correct opinions on the subject are most important, and that the acquisition of them is neither difficult nor repulsive.

The following Papers were read :—

1. *On Mining Royalties and their effect on the Iron and Coal Industries.*
By Professor W. R. SORLEY.

§ 1. *Historical.*—Local customs still existing in various parts of England and Wales point to a condition of things in which extensive rights to the working of minerals were possessed by the inhabitants of mining districts. But English law favoured the extension of the rights of private property at the expense both of such communal rights and the claims of the sovereign, till possession of the surface became the best *prima facie* claim to possession of the minerals underneath, and the legal maxim was adopted, *Cujus est solum, ejus est usque ad cælum, et deinde usque ad inferos*. The same tendency to private ownership was checked or reversed in most European countries by the French Mining Law of 1791 (re-enacted in 1810), which nationalised the minerals, and allowed of their being worked only on concession from the State.

§ 2. *Descriptive.*—The exhaustion of mines by working induces the private owner or landlord to charge the lessee or worker of the minerals (1) a royalty or tonnage-rent on the quantity of mineral removed; (2) a fixed or certain rent, to provide against the amount of his royalties falling below that sum; and, in some cases, (3) rents for instroke or outstroke, shaft, and wayleave, also calculated on the tonnage or royalty principle. An estimate of the amount of these rents and account of their variations can hardly be given in an abstract.

§ 3. *Incidence of Royalties: Opinions of the Trade.*—The following summary may, I think, be taken as fairly representing the views of those engaged in the trade who have expressed their opinions on the subject:—

(1) That royalties, being a fixed money payment for quantity of output, are heaviest just when trade is depressed and prices low;

(2) That English trade is at a disadvantage in competing with foreign countries where there is little or no royalty to pay;

(3) That it is unfair for the landlord's rent to remain undiminished when the wages of workmen are being reduced, and the profits of the employer disappear; and even—a platform sentiment—that it is unjust for the landlord to claim any share of the minerals under his land, seeing he did not put them there.

§ 4. *Economic Theory of Royalties.*—The theory of mine rents is usually treated by economists as on a par with that of agricultural rents (Ricardo's 'Works,' p. 45, Bagehot's 'Economic Studies,' p. 127), though attention may be drawn to the fact that the mine is exhausted by working. Now, if the rent of a mine is determined in the same way as that of a farm, rent will not enter into the price of the product at all, so that its abolition would not cheapen coal and iron, but only enrich certain mining lessees, while its nationalisation would not affect the mining industry any more than the confiscation of any equal amount of other property would. But farm-rents and mine-rents have to be treated differently, owing to the fact that the farm is not exhausted by workmanlike cultivation, whereas the mine is exhausted by being worked. Thus, when the economist says of agricultural rent (1) that the 'worst land' cultivated (expenses of production on which determine the price of the product) pays no rent, or (2) that the produce yielded by the last application of capital and labour to the soil (that application which the farmer is only just induced to make) pays no rent, the same cannot be affirmed of mines. (1) The 'worst mine' worked does pay a rent, because it is not indifferent to the landlord whether his property be disfigured, and a possible future source of income exhausted. (2) The produce of the 'last application' of capital and labour to the mine pays the same royalty per ton as any other portion of the yield. The theory still holds, that the price of the product is determined, in the long run, by its expenses of production in the least advantageous circumstances, i.e. in the 'worst mine.' But this worst mine pays a rent or royalty which therefore enters into price. This royalty paid by the 'worst mine' may be called the *minimum royalty*, and is a part of expenses of production. Any royalty higher than this, in so far as it is higher, does not affect price, but is a payment from tenant to landlord for the exceptional advantages of a particular mine.

§ 5. *Economic Theory and the Facts of Trade.*—A minimum royalty, such as the above, seems to be discoverable. The materials at my command lead me to suppose that the minimum royalty (the smallest met with in cases sufficiently important to determine the result) is in this country about 4*d.* a ton for both coal and ironstone. And, although day by day in actual trade, it is not the expenses of production on the worst mines that fix the price, and it is rather prices that determine what mines can continue working; yet, in this way, the expenses of production on the worst mines which keep going become a measure of prices: these expenses include the minimum royalty, and the minimum royalty is thus a factor in price.

§ 6. *Effect of Royalties on International Competition.*—Even 4*d.* a ton on the raw material will add considerably to the price of a product such as pig-iron—will probably amount to about 1*s.* 8*d.* a ton on Cleveland pig. Hence there is ground for the assertion that royalties put England at a disadvantage in competing with foreign countries. Yet there is a certain illusoriness about the so-called ‘no-royalty’ system abroad. It is not true that royalties are entirely absent in the cases of our great competitors, France, Germany, and Spain. (1) In these countries certain dues are paid to the State—almost nominal in Spain, 2 per cent. of gross value of output (of coal) in Germany, 5 per cent. of net produce (coal or ironstone) in France. Further, in certain districts of Germany, old seigneurial rights still exist, and in France a *redevance tréfoncière* has to be paid to the owner of the surface. In most cases this is of merely nominal amount, but in other cases it is a tonnage rent, and, in some districts (e.g. the coal mines in the basin of the Loire), is as much as 4½*d.* to 6½*d.* a ton. (2) A concession gives absolute ownership to the concessionaire, who may, and often does, sublet the working of the mines at a royalty. For instance, the Orconera Co. pays a heavy royalty to the original concessionaire for the famous Bilbao mines. Perhaps this subletting at a royalty is commoner in the case of the richer mines, and does not occur in the poor. If so, English mining industry will be more heavily burdened than continental by the excess of its minimum royalty over the State and other dues paid abroad. Further, it is to be noted that it is not the smaller royalties that account for the recent success of the German iron trade, but the discovery of a process of conversion into steel which can be applied to the German iron.

§ 7. *Proposed Reforms.*—The complete subversion of the present system is sometimes proposed. It could be carried out in either of two ways: either by the abolition of mining rents and royalties, or by their nationalisation. The latter would enrich the national exchequer without specially affecting mining industry; the former would reduce prices by the amount of the minimum royalty, and so stimulate demand, and would make a present to existing lessees of the remainder of the royalties they have contracted for. It would thus favour the lessees of good mines at the expense of the lessees of poor mines, and lead to a new distribution of trade (remove, for example, the coal trade of Northumberland and Durham to South Wales). For this reason (apart from weightier political objections) such a measure seems undesirable. The real grievances of our present system rather appear to be in (a) the royalty payment remaining the same while prices fall; (b) the high certain rents and the limitation of time for working ‘shorts’; and (c) the tonnage charges made for instroke and outstroke, shaft, and wayleave. In the last class of cases the tonnage principle is out of place. The owner of a way (or of a royalty next to a mine which may not be worked by shaft) has an advantage of position which enables him to obtain a monopoly price. There is no pretence of fairness in the contract which exacts a penny a ton (amounting, in the case referred to, to 600*l.* a year) for leave to draw stone under a field forty yards wide. Considering the national importance of the mining industry, and the way in which it is burdened by such charges, Parliamentary interference would seem as allowable here as when it compels the sale of land to a railway company at a valuation. A remedy for the two former grievances might be carried through without affecting prejudicially the interests of landlords, but it is doubtful whether anything but the coercion of an Act of Parliament will secure its adoption. The reforms in the royalty system which thus seem to be called for would be effected by a law enacting—

(1) that instroke or outstroke, shaft, and wayleave rents should be granted at a fair valuation of the land occupied or damaged, or of the injury done to the ventilation, drainage, &c., of the mine;

(2) that in all future leases—

(a) there should be no restriction put on the time for working shorts;

(b) the royalty charged should be a percentage of the value of the output.

No mining court would be necessary for carrying out such reforms; nor does there seem to be, in the defects of the present system, any sufficient reason for transferring the assessment of royalties from private agreement to the decision of such a court.

2. *The Relations Between Sliding Scales and Economic Theory.*

By L. L. PRICE, M.A.—See Reports, p. 523.

3. *On Wage Statistics and Theories.* By JAMES MAVOR.

This paper (1) describes briefly past and current theories of wages; (2) illustrates the course of wages by reference to American and English statistics; (3) recounts the leading causes of wage fluctuations; (4) offers analysis of existing method of distribution of the product; (5) points out resulting criticism of current theories of wages; and (6) attempts classification of proposals for effecting changes in the current method of the distribution of the product among the contributors to production.

4. *The Growth of American Industries and Wealth.*

By MICHAEL GEORGE MULHALL, F.S.S.

The development of the United States in ten principal items since 1850 has been as follows:—

	1850	1860	1870	1880	1888	Increase since 1850 (per cent.)
Population	100	136	167	213	270	170
Commerce	100	214	208	477	415	315
Agriculture	100	162	189	293	352	252
Manufactures	100	186	312	421	508	408
Wealth	100	227	369	614	780	680
Steam-power	100	225	325	527	785	685
Shipping	100	156	151	158	174	74
Railways	100	340	585	1,035	1,680	1,580
Banking	100	190	470	795	1,018	918
Education	100	140	164	232	306	206
Total	1,000	1,976	2,940	4,770	6,288	5,298

The foregoing table is according to the census reports from 1850 to 1880, and estimates for 1888.

In order to arrive at the working-power, we allow 300 foot-tons daily for each male between fifteen and sixty years, 200 for each female, 3,000 for each living horse, and 4,000 for each horse power of steam. The result is as follows:—

Millions of foot-tons daily

	1850	1880
Human	3,160	6,850
Horse	12,990	31,090
Steam	6,440	33,740
Total	22,590	71,680

At present the aggregate of energy reaches 90,000 millions of foot-tons daily, which is more than the collective force of the United Kingdom and France.

Measuring each of the principal industries by the number of hands, we find the increase as follows:—

	1850	1880	Increase
Agriculture	3,311,000	7,671,000	130 per cent.
Manufactures	958,000	2,733,000	184 „
Trades, &c.	2,923,000	6,988,000	140 „
Housekeeping	3,362,000	8,956,000	168 „
Total	10,554,000	26,348,000	150 „

But the increase of hands is by no means a fair measure of the growth of the above industries.

1st. As regards agriculture, the grain crop rose from 867 million bushels in 1850 to 2,697 millions in 1880, an increase of 211 per cent. The production of meat rose from two million tons to three and a half millions. The value of agricultural and pastoral products rose from 213 millions sterling to 562 millions sterling, viz.:—

		Millions sterling	
		1850	1880
Grain		94	293
Meat		44	88
Cotton		19	67
Sundries		56	114
Total		213	562

The assessed value of farms and stock rose from 937 millions in 1850 to 2,973 millions sterling in 1880, being an average increase of 147 per head per annum on the mean number of persons engaged in all manner of agricultural or pastoral pursuits.

2nd. As for manufactures, the value of merchandise produced rose from 212 millions in 1850 to 1,117 millions sterling in 1880. But the values in 1880 were artificially enhanced 25 per cent. by the protective tariff, and therefore the real value in 1880 was only 893 millions sterling, showing an increase of 321 per cent.

3rd. Commerce, that is, imports and exports (not including bullion), rose from 65 millions to 310 millions sterling. The shipping trade has, however, fallen away, the American carrying power being now less than the British, whereas in 1850 it was greatly in excess, viz.:—

		Carrying-power, Tons	
		United States	British
1850		5,640,000	3,955,000
1886		9,820,000	22,770,000

The United States, meantime, have made great progress in railways, possessing at present 151,090 miles, against 9,000 in 1850.

Banking business has multiplied tenfold, the total of banking capital and deposits in 1883 showing 754 millions sterling against 74 millions in 1850.

INCREASE OF WEALTH.

This has been greater than the growth of industry, and four and a half times more than the increase of population. The census returns show—

	Millions £ sterling
1850	1,484
1860	3,861
1870	5,003
1880	9,077

The increase in thirty years averaged 258 millions sterling per annum, or 50 per cent. over the accumulations of Great Britain or France. It averaged 14l. per worker, or 7l. per inhabitant, yearly over the whole period. The accumulation of thirty years showed—

	Millions £
By Americans	6,230
„ Irish settlers	471
„ German „	374
„ Other „	518
	<hr/> 7,593

The components of this increase of wealth in thirty years, according to the census returns, were—

	Millions £
Farms	2,036
Railways	981
Factories	472
Houses, &c.	4,104
	<hr/>
Total	7,593

The accumulations averaged 7l. per annum per inhabitant in the decade ending 1860, less than 5l. (4·7) in that ending 1870, and over 9l. (9·2) in that ending 1880.

The census for 1890 will probably show a population of 66 millions, with an aggregate energy of nearly 100,000 millions, for foot-tons daily, and an accumulated wealth of 14,000 millions sterling, figures never before applicable to any nation in the world.

5. *Somersetshire Cider.* By JOHN HIGGINS.

Economic science cannot confer a greater benefit on the county of Somerset than by indicating the direction in which sound scientific methods can be brought to bear on the natural products of the district.

The old 'rule of thumb' methods, as they are called, have grown out of the experience and thought of generations of workers. And it not infrequently happens that what looks like superstitious observance of old ways turns out to be in real accordance with the soundest science.

Economic science, with its handmaiden, recorded statistics, steps in to examine accurately the work we do; to separate the sound, good rules of work from the clumsy, irrational ones; to point out the course leading to real improvements; and to record what has been done in these directions for our future guidance.

In the short paper submitted it is not claimed that any finished scientific improvements in the making and storing of cider are brought forward. The more humble office of the writer is the description of the old-fashioned ways, of showing improvements which the experience of years has suggested to him, and of asking that the attention of practised chemists and others may be brought to bear on the cider industry of Somerset, in the hope that *light*, and if possible by all means *sweetness*, may be thrown upon and added to our west country beverage.

The writer shortly describes the making of cider as practised in Somerset, its qualities, the fermentation and development of aroma, its alcoholic strength, and the malic and acetic acids and fusel oil found in it.

The probable sources of the natural yeast cells, and methods suggested for the cultivation of pure yeast cells on the lines indicated by Hansen of Copenhagen and M. Pasteur, are touched upon.

The statistics of the subject can only be slightly handled, since no reliable data exist upon which accurate calculations can be made.

It is hoped that under the new Minister of Agriculture there may be better data in the near future.

6. *Agricultural, Commercial, Industrial, and Banking Statistics.*

By WM. BOTLY, *M.R.A.S.E.*

Comparative statistics are given of the leading features of industries and interests above mentioned, showing the high position occupied by the United Kingdom as compared with other nations. It is shown that the capital of the United Kingdom employed in banking was, in 1882, 840,000,000*l.*, or 29,000,000*l.* more than the amount so employed by France, Germany, Austria, and Russia combined, and that Great Britain has nearly 10 per cent. of her national wealth engaged in banking.

FRIDAY, SEPTEMBER 7.

The following Papers were read :—

1. *An Analysis of the Current Conception of State Socialism.*

By Professor HENRY SIDGWICK, *M.A.*

The present tendency of opinion is towards increased interference of Government. The results of this are often lumped together and referred to 'State-Socialism,' as opposed to 'Individualism,' or *Laissez Faire*—the principle that 'individuals if secured from interference can take better care of their own interests than Government can for them.'

My present object is to distinguish different issues that are liable to be confounded in this opposition.

I. A great deal of recent extension of governmental interference is really individualistic in principle; its aim is the more effective protection of individuals from mischief to person or estate caused by action of other men, intentionally or carelessly.

Most individualists recognise that it is the duty of Government to prevent this kind of mischief; and it is easy to see how the progress of civilised states brings new occasions for interfering in this way, either

- (a) From new or increased dangers due to the closer massing of human beings and the more complicated relations which development of industry and civilisation bring with it; or
- (b) Increased insight into such dangers; or
- (c) New knowledge of possible remedies due to progress of science.

Illustration—Sanitary interference.

II. Even when Governmental interference, actual or proposed, cannot be based on the individualistic principle, it does not necessarily imply a denial of the proposition that 'the individual is the best guardian of his own interest'; but only of the quite different proposition that 'the common welfare is best attained by each seeking his own interest intelligently.'

This latter proposition I hold to be largely true; but there are many exceptional cases, as I pointed out two years ago at Birmingham—*e.g.* :

- (1) Where the individual cannot adequately appropriate and sell the utility he might render to society; or
- (2) Where the process of sale is wasteful of time and labour; or
- (3) Where a business tends to become a monopoly, since a monopolist may often get better pay for less service; or
- (4) Where uniformity of action or inaction is specially important.

Much of the actual industrial intervention of Government is justified on one or other of these grounds—*e.g.* regulation of forests, fisheries, management of conveyance and communication, currency, provision of gas and water.

Is all this to be called Socialistic, when its aim is to benefit the community as a whole, not one class at the expense of another? Certainly 'Socialistic' is often understood to imply a design of benefiting the poor at the expense of the rich.

No doubt much expenditure of public funds in modern states has apparently this latter object—*e.g.* on education and poor relief.

III. Here, however, the distinction is important between

- (1) Taking A's products to supply B's needs ;
- (2) Equalising opportunities of productive labour—*e.g.* by State-aided education.

This latter is defensible on individualistic principles as rather increasing than diminishing stimulus to self-help. Still, it is urged, this equalisation costs money. A's products have to be taken to enable B to produce more, and this is contrary to natural justice. But it is fair to answer that on the principle of individualism, it is only the appropriation of the results of labour, not of natural resources, that is absolutely justifiable ; and that, by the actual appropriation of natural resources—however practically inevitable—the propertied classes have diminished the opportunities of the unpropertied to an extent that justifies a demand for compensation ; and that State-aid to education, emigration, &c., regarded as an attempt to give this compensation, is not anti-individualistic if the taxation it involves does not seriously diminish the inducements to labour and thrift of the persons taxed.

IV. Public poor relief must be admitted to be socialistic in case (1), though its bad effects are materially reduced by the workhouse system.

Here, again, a distinction seems needed in comparing compulsory poor rates with compulsory insurance. It is disputed which interferes most with the liberty of the individual. Perhaps we may say that the latter involves greater *political* interference, the former greater *economic* interference.

2. *The Transition to Social Democracy.* By G. BERNARD SHAW.

INTRODUCTORY.

The Mediæval Order of custom and rule. Its disablement by the growth of commerce and by the industrial revolution. Modern Political Economy and the abandonment of industry to competition. Discovery of the nature of economic rent. Modern Socialism. The practical transition involved in its adoption. The political conditions of that transition. Democracy the complement of Socialism. Social Democracy. Agitation for effecting a change at once by violence. Practical necessity for a gradual transition.

PROGRESS OF THE TRANSITION UP TO THE PRESENT TIME.

Starting-point—the Reform Bill of 1832 and the abolition of the old Poor Law. The resultant social pressure. Its effects—the Income Tax and the Factory Acts. Free Trade and Emigration. The gold discoveries and the period of prosperity. The pressure relieved. Apparent successes of 'self-help,' and collapse of Social-Democratic agitation. The Reform Bill of 1867. Successes of State enterprise—the Post Office and the Education Act. End of the period of prosperity and return of the pressure. Revival of Socialism.

THE FUTURE.

Completion of the Transition.

Starting-point—the Reform Bill of 1884. The remaining practical steps to the consummation of Democracy—(1) to perfect the constitution of the Democratic State ; (2) to adapt its machinery to the organisation of industry. Why these steps will be taken. The agitation for the municipalisation of urban rents. Impossibility of permanently resisting it. Its reinforcement by the Land Nationalisation movement and the demand for a Progressive Income Tax. The weak point in these schemes. State organisation of industry inseparable from State custody of rent. The point at which this will begin—the *fighting-point* of the transition. Effect of exportation of capital on the labour market. The unemployed and the local authorities. The extension of municipal enterprise to general industry. Its

methods of acquiring capital, land, ordinary labour, and managerial ability. Economic reaction of these methods. Municipal advantages in competition, extending even to the destruction of rents both of land and ability. Gradual extinction of the proprietary class. Relation of the municipalities to the central government. Consummation of Social Democracy.

3. *The Tendency of Competition to result in Monopoly.*
By PROFESSOR FOXWELL.

4. *Associative Economics applied to Colonisation.* By W. L. REES.

The question of emigration is daily becoming more important to Great Britain.

The yearly increase of her population and the serious diminution in the numbers of labourers employed in agriculture, as well as the severe competition of foreign manufactures, render it necessary that some provision should be made to transplant the unemployed to the Colonies for the purpose of settlement upon the waste lands.

In olden times migration took place either by nations or by communities. In the Middle Ages by communities only, which system, under the name of special settlements, has been largely practised till the present time, although individual emigration has in modern days become greatly predominant. The large majority of those to whom emigration is now necessary are unable thus to leave the United Kingdom by reason of poverty. They are also unwilling by reason of fear of the sea and the unknown land, and of being obliged to recommence life among strangers without any certainty of help or success.

They are for the most part unfit also; they do not possess the energy, courage, aptitude, and self-reliance necessary to make successful colonists, such as belonged to the earlier and bolder men who have raised new Englands in the outlying parts of the empire.

Nor are the circumstances which surround immigrants in these days so favourable to individual settlement as of old. The available land near the harbours and centres of population is all gone. Employment is not so plentiful as in earlier days, and the operation of our present economic laws is causing the reproduction to some extent in most of the Colonies of the difficulties which harass older countries.

The only method of colonisation likely to be successful is the associative or co-operative method, by associations registered under the Joint Stock Companies Act, in which the capitalist, the labourer or producer, and the consumer or purchaser should be joined together as partners:—

The capitalist to receive a moderate interest and a share of profits and increased values;

The labourer, including all employed by the association, to receive wages or salary and a share of the profits and increased values;

The consumer or purchaser to receive his goods and a share of the profits and increased values.

The capital would be secured upon the property, and expended in making it productive, and therefore of value.

Production to be on a large scale, and markets secured, either through the co-operative bodies now existing or others formed upon the same lines.

Going in companies to a certain destination upon certain and constant employment, only dependent upon good behaviour, and with a certainty of sharing in profits, the future would look bright enough, and hope would give fresh life and vigour.

This plan of colonisation would open many avenues for the utilisation of idle lands by idle labour; would relieve the ratepayers from much, if not all, of the poor-rates; would increase commerce, strengthen the Colonies, produce fresh wealth,

give a practical imperial federation, and point out a practical system of co-operation between Capital and Labour which might ultimately confer safety and comfort upon civilised society.

5. *On the Statistics of Examination.*¹

By Professor F. Y. EDGEWORTH, M.A., F.S.S.

The object of this paper is to estimate the error incident to a large aggregate of marks at a competitive examination in several subjects. Error is defined as deviation from that Mean towards which the average marking of numerous competent critics would tend.

Among the sources of error are: I. The fact that there is a *minimum sensible* in our perception of degree of merit. II. The idiosyncrasy or personal equation of the examiner affecting (1) particular answers, (2) the scale of marks in any subject. III. The negligence of examiners.

The extent of the several errors is estimated by means of statistical data. Compounding the items according to the rules of the Calculus, the writer finds a 'probable error' of 2 per cent. (corresponding to a possible error of more than 6 per cent.) in the aggregate of marks according to which candidates are classed at an examination of a kind now prevalent.

That is the error in appreciating the work done at the examination. A further error is incurred in taking that work as a sample of the candidate's real proficiency. Upon a certain mechanical hypothesis, a part of this latter error can be estimated by the Calculus of Probabilities. Adding this error to the previous account, we may infer that the number of candidates displaced—that is, not obtaining a prize when they ought, or obtaining one when they ought not—is likely to be about 30 out of a total of 1,000 examined.

The following recommendations are based on statistical grounds: (1) The order of merit within the Honours Class should be abandoned whenever the difference between the marks of the discriminated candidates is less than the 'probable error' incident to those figures. (2) It might be expedient that the examiners should at first scrutinise only *half* the answers of each candidate, wherever the purpose of the examination would be subserved by obtaining a rough preliminary indication of the order of merit. (3) In order that the importance assigned to each subject may be free from accidental oscillation, it would be allowable to assume that the average proficiency of a large number of candidates in any subject is, from year to year, constant (just as the average height is); and, therefore, that the mean of the marks in that subject should be the same every year. If the average of the marks given to a number of candidates by any examiner differ from the figure which may have been prescribed for the mean, those marks should be reduced to the normal scale. The practice of basing the standard upon the answering of the most proficient candidate is objectionable. (4) For a certain purpose it might be theoretically desirable to combine the marks in different subjects, not by simple addition, but by taking their geometrical mean.

SATURDAY, SEPTEMBER 8.

The following Papers were read:—

1. *The Revenue System of the United States.*² By ALBERT SHAW, Ph.D.

The United States enters upon the current fiscal year with an interest-bearing debt reduced below \$1,000,000,000. In 1865 the bonded debt was approximately \$2,400,000,000. Sixty per cent. of the principal has been wiped out, and 75 per

¹ Published *in extenso* in the *Journal of the Royal Statistical Society*, Sept. 1888.

² Published in the *Contemporary Review*, Nov. 1888.

cent. of the yearly interest-charge has disappeared. The rapid debt payment has now been brought to a halt by the cancellation of all matured obligations and the high premiums commanded by the outstanding bonds, about one-fourth of which become payable at the Government's option in 1891, while the remainder do not mature until 1907.

Before the war the U.S. Government was depending upon customs' duties for its revenue. Fluctuations of trade subjected the public income to inconvenient variations, and the need of a second principal source of income was obvious. The heavy cost of the Civil War compelled the creation of an elaborate system of internal taxation—including excise, income, stamp, banking, and other taxes. The outgoings of the four war years aggregated \$3,350,000,000. Current revenues contributed about \$730,000,000 towards this sum, of which the larger half came from the internal taxes. After the war the unpopular income-tax was abolished, and by gradual remissions the 'internal revenue system' was reduced to the proportions of an excise-tax upon spirits, tobacco, and fermented liquors, which produces nearly two-thirds as much revenue as is derived from the customs.

The annual surplus income exceeds \$100,000,000. In the fiscal year 1886-7 there were called in and cancelled \$125,000,000 of matured bonds, drawing 3 per cent. interest. Less than \$34,000,000 of this class of bonds remained to be paid in the year 1887-8. They were soon extinguished, and the country was embarrassed by the accumulation in the Treasury of large sums of the circulation medium. The stringency was relieved by the deposit of Government funds with banks throughout the country, and by the purchase on public account in open market, at high premiums, of about \$45,000,000 of the unmatured bonds, half of them being bought at an average price of more than 125.

It is agreed that the volume of revenue ought to be reduced at once. This would be an easy thing to accomplish if advantage were not taken of the situation by those desiring to force a reform of the revenue system. The reduction of surplus revenue should be accomplished first upon a plan that would secure unanimous consent. Then the question of tariff and revenue reform could be properly taken up. The current discussion is likely to end in a measure that will merely reduce revenue without affecting the essential character of the revenue system.

The Federal Government is to be regarded as practically restricted to indirect sources of taxation, other sources being in the hands of the States and municipal corporations. The main dependence for revenue must continue to be a tariff upon imports. Good financiering also requires the maintenance of the excise system as a supplemental source of income.

There seems little reason to believe that in arranging the tariffs of the future the protection principle will be abandoned, however much the existing duties may be revised and modified. The pending Mills' Bill places a few articles, chiefly crude materials for manufactures, upon the free list, and reduces the average rate of duty upon the remaining articles of the tariff-list from about 47 per cent. to about 42 per cent.—by no means a revolutionary proposal.

The tariff should be revised by an impartial, permanent Commission, acting in the light of information to be supplied by exhaustive and thoroughly scientific statistical inquiries. Until such investigations are made, the real operation and effect of the American system, whether as a system of taxation or as a system of protection, can only be a matter of opinion and assertion; it cannot be a matter of demonstration.

2. *On the Distribution of the Licences proposed to be transferred in aid of Local Expenditure.* By R. H. INGLIS PALGRAVE, F.R.S., F.S.S.

This paper is based on the statements respecting the licences dealt with by the Local Government Bill of this year contained in the Memorandum, dated June 21, 1888, prepared by the Local Government Board. The licences referred to were those on publicans and all other licences for retailing beer, spirits, wine, &c., and also those on carriages, male servants, armorial bearings, &c.

The licences on game dealers, tobacco dealers, appraisers, auctioneers, house

agents, pawnbrokers and plate dealers, which are also stated in the Memorandum, are not included in the tables given in this paper, as it was not possible to apportion them in a satisfactory way between the two heads of expenditure which are the subject of the present investigation.

The Author has taken the amounts raised under the two general heads mentioned above, in each of the municipal boroughs and counties of cities included in the statement—all of which, with the exception of York, Exeter, Lincoln, Chester, Gloucester, Worcester, and Canterbury, had populations exceeding 50,000 at the last Census. These places were forty-nine in number. In the case of one, West Ham, the investigation could not be carried out in the same manner as the others, as the published returns do not supply the value of the assessment.

The method of investigation followed in the paper is to compare the amounts raised by the two different descriptions of licences, which may roughly be taken to indicate the expenditure of the working classes and of the wealthier classes of the population respectively, both with the numbers of the population by whom it is presumed these duties are paid, and with the wealth of each place as indicated by the assessment value—the object desired being to ascertain whether the incidence of these duties is in any way uniformly distributed over the country. The facts, as indicated by the tables annexed to the paper, indicate that this is far from being the case.

Thus, taking the maximum amount contributed by the publicans' licences, in proportion to population, in the place where these duties are the heaviest, namely, Nottingham, at 100; the minimum, in the place where they are the lightest, namely, Wolverhampton, is 26. The same results, nearly, are shown when these duties are compared with the assessable value. Taking the maximum, in Norwich, also at 100, the minimum, in Salford, is 24.

The results of the carriage, &c., licences are even more unequal, comparing these in the same manner with the population, and the maximum, in Worcester, at 100, the minimum, at South Shields, is 2. Comparing these same duties with the assessable value, and taking the maximum, at Chester, at 100, the minimum, at Salford, is 7.

The inference which may be drawn from this inquiry is, that the incidence of these taxes is far from being uniform over the whole of the country, and the advisability of further investigation into the question of the incidence of taxation becomes obvious. The amounts dealt with in the present paper are, comparatively speaking, small, and a wider inquiry is desirable.

3. *The Standard, or Basis, of Taxation.* By CLAIR J. GRECE, LL.D.

The thesis to be upholden is that neither capital nor income, but expenditure—that is to say, destructive expenditure—is the right standard, or basis, for fiscal computation, and the abstract of the memoir was as follows:—

The contributions of the various members of the State to its burdens, or charges, must be unequal. This fact is apparent from the inequality of the means and resources of the contributories, and is, indeed, implied in the very term *taxation*, or assessment; for, were the contributions all alike, it would be a payment, but it could not properly be called a *tax*. From this palpable inequality of resources in the contributories has probably proceeded the common and erroneous opinion, to which even the clear and penetrating mind of Adam Smith would appear to have yielded, that the contributions should be proportional to the means or resources of the contributories. Combined with this opinion another principle has been industriously at work, that many members of society are in the possession of means largely in excess of their rational needs, and that this excess may be legitimately drawn upon for the purposes of the State, a principle which finds its expression nowadays in the demand for graduated imposts upon successions and upon incomes. But the principle to be established is that, in apportioning the burdens of the State among the contributories' rights, the diversity and the inequality of means and resources should be disregarded as impertinent. The

proper principle is that *each contributory should give to the State in the proportion in which he receives from the State*; and this proportion is not, as would at the first aspect appear just, to be calculated either upon the still *fluid means*, or incomes, of the contributories, or upon their *means solidified*, and stored up as *capital*. What the citizen receives from the State is the *fruition*, or enjoyment, of his means or resources under the State's guarantee; but the perception of income, whether in the shape of wages, of profit, or of rent, is not its *fruition*, or enjoyment. To illustrate the meaning, let us reduce the problem to its simplest terms, and suppose two members only of a political society, and that the labour of both is equally valuable, which means that their contributions to the aggregate of the means of enjoyment are equal. Let one, A, consume as fast as he produces, while the other, B, forbears from consuming a moiety. A has under the State guarantee double the fruition that B has. The burden of proof now lies upon whosoever should assert that their contributions to the State burdens should be alike. It would perhaps be maintained that, notwithstanding the actual inequalities of fruition, the potential, or facultative, fruition of both was equal, that it was open to B to *consume*, and by consumption to *enjoy* equally with A. But, through the abstinence of B, another party, C, comes upon the scene. B by his abstinence has afforded the means of enjoyment to C; and C, too, is a member of the political society, and should therefore be a contributory to its burdens. But if the whole contribution to the State had already been rendered by A and B, C would escape the burden altogether. This is the *reductio ad absurdum* of the taxation of income. The taxation of destructive expenditure—that is, of consumption—entails no absurdity; but A, whose production and consumption equal each other; B, whose production exceeds his consumption; and C, whom we may treat abstractedly as a pure consumer, all contribute in the proportion of their fruition or enjoyment under the State guarantee.

But, if the contributions to the State ought not to be measured by the incomes of the respective contributories, still less should they be graduated according to their accumulated capitals. Capital is deposited, or solidified, income. Its end is the generation of enlarged fluent income; and income, whether original, that is, generated by labour alone, or derivative, that is, generated by labour in conjunction with capital, is *not the end*, but the *means* to the *end*, the end being ever the fruition, or *enjoyment*, in the eventual expenditure of the income. By introducing capital we import another term, but a term which, in the order of causation, precedes income, as income precedes consumption, or fruition. The order is (a) capital, (b) income, (c) expenditure, (d) consumption or fruition. By imposing a tax upon income you strike in the wrong place; but by taxing capital you strike still further from the mark. Only by assessing taxation upon consumption—that is, upon the destructive expenditure by the members of the political society—do you collect the contributions from the parties who ought to contribute, and in their due proportions. That the characters which have been assigned severally to A, B, and C may be filled in successive acts of the drama of society by the same persons, or by persons succeeding to the same rights, makes no difference to the argument. The frugal B may be followed by a spendthrift heir, who dissipates B's accumulations. The spendthrift would then, under a properly adjusted scheme of taxation, become the contributory to the State charges in the proportion of his fruition, or of his destructive expenditure.

The State machine is not concerned to promote or foster either accumulation or expenditure. Accumulation means, virtually, enjoyment postponed, or deferred; while consumption is enjoyment in act; and the function of the State is to guarantee the enjoyment and to maintain its neutrality between the present, or actual, and the postponed, or deferred. But it is only by assessing its burdens in the proportion of the destructive expenditure of the members of the political society that it maintains its neutrality. By taxing income it imposes equal burdens upon A the spendthrift and B the accumulator, unduly strengthening the motives actuating A, and equally unduly weakening those actuating B—that is to say, *encouraging present* at the cost of *deferred* enjoyment; whereas, by taxing A and B according to their consumption or destructive expenditure, A contributes in the pro-

portion of his fruition under the State guarantee, B also in the proportion of his, and C, the postponed or deferred enjoyer, contributes his quota, when the stage of enjoyment is reached.

4. *The Suitability of Small Towns for Factory Industries.*

By RUSSELL R. TANNER.

The limitations of the paper.

I. *The Employer's Position.*—Among the disadvantages are: Inability to suddenly increase the staff and so meet unexpected or urgent requirements. Distance prevents so close a watch on the pulse of the market. The cost of carriage a constant drain on profits. There is a tendency to get behind the times and miss opportunities and improvements. To correct this, constant watchfulness needed. Among the advantages are: The considerable value of a man's personal integrity as a negotiable article. Low rents and wages and the consequent reduction in the cost of production and warehousing. Less temptation to speculate on rising or falling prices and consequent freedom from anxiety and worry. The deviations in prices smaller, and the mental strain attending both rises and falls in prices less marked. Greater influence over employes. A more serious thing to lose a situation from bad conduct in a small town. Better discipline can be maintained, and consequently more work done.

II. *The Employé's Position.*—The so-called disadvantage of lower wages a chimera. Real wages compared with nominal wages. Allotments, decrease of illness. Longer working capacity taken into account. Other advantages are: Working rooms more healthy. House rents low, so that everyone can afford a house. Temptations less powerful. Less liability to loss of situation, hands being hard to replace, short hours are worked by preference.

III. *Advantages Common to All.*—Improved health, consequent increase in earning power. Classes less sharply divided; great benefits result from this. The standard of living lower. The constant travelling avoided. Recreations more rational. Life carried on at a lower pressure. Increase of neighbourly feeling. Example more potent for good, less potent for evil. Increased self-respect. Conclusion.

MONDAY, SEPTEMBER 10.

The following Reports and Papers were read:—

1. *Second Report of the Committee on the method of ascertaining and measuring Variations in the Value of the Monetary Standard.*—See Reports, p. 181.
2. *Index Numbers as illustrating the Progressive Exports of British Produce and Manufactures.* By STEPHEN BOURNE, F.S.S.—See Reports, p. 536.
3. *Report of the Committee on the Statistical Data available for determining the amount of the Precious Metals in use as Money in the Principal Countries, the chief forms in which the Money is employed, and the amount annually used in the Arts.*—See Reports, p. 219.
4. *An Examination into the Reasons of the Price of Wheat Rising or Falling contemporaneously with the Variation in the Value of Foreign Currencies.* By W. J. HARRIS, F.S.S.

* This paper commences with a preamble demonstrating the effect on prices and production in a hypothetical case of a new country being discovered with iron as its

precious metal and wheat as its most easily-produced article of export. Mr. Harris attempts to show that, if the coinage in such a country were open to all comers, the cost of wheat to an importing country like England (which has an unlimited supply of iron at a very small cost of production) would be very little beyond the freight and insurance. He argues that in such a case the merchants would have an enormous profit, and that the effect produced would be a rise of price, and consequently a great impulse to production of wheat in the new country, and a gradual fall in the price of wheat in England until no other exporting country could afford to compete.

He points out, however, that if the coinage of the iron were restricted by the Government of the new country, and, in fact, kept in the hands of that Government, the main part of the profit on export would remain in the hands of the new country, and that the exchange of commodities would only take place to the extent of the actual requirements of the people, thereby limiting the growth of wheat to what they would require in other goods and to the amount of fresh coinage which the Government might allow.

Following this hypothetical preamble, Mr. Harris compares the circumstances of the United States, where the Government keeps coinage entirely in its own hands, and those of India, where the coinage and the consequent inflation of currency is open to all. He arrives at the conclusion that there is a real premium on production in India to the extent of the fall in value of silver, whereas there exists no such premium in the United States. Then, taking the case of Russia, a paper currency country, he attempts to show that she has superior chances of production as compared with India. In fact, that so much as the paper rouble is depreciated beyond the price of its silver representation, so great is the premium to the grower of Russian wheat over and above any premium which the Indian grower may enjoy. The paper leads to the conclusion that any important legislation which raised the value of silver would in no way necessarily affect the value of the Russian currency, whereas it would affect the value of the Indian rupee, and that we might see the trade of India to a large extent transferred to Russia and other countries where the currencies were independent of the value of metals with an unvarying mercantile value.

5. *The Effects on Indian Exports of the Fall in the Gold Price of Silver.*
By L. C. PROBYN.

The paper states that the gold price of silver has fallen from 60½*d.* in 1871 to 42*d.* an ounce at the present time, and alludes to the encouragement thus said to have been given to the competition of Indian with English produce and manufactures. It is then shown that the great flow of silver to India, and the general rise in silver prices, which Mr. Bagehot and others predicted would result from a fall in silver, and which they thought would give a great stimulus to the Indian export trade, have not occurred. The exports of the 18 years between April 1, 1870, and March 31, 1888, are then examined, two tables being prepared showing the figures of the first and last years of the period, and the increases and decreases in the quantities and values of the 13 principal articles of export in each of the intervening years. It is first shown that the actual increase in values is not so great as in the 17 years preceding 1870-71, though a much higher average annual increase might have been expected. An examination is then made of the growth of the total value of the trade during each five consecutive years, which shows that the greatest growths have occurred in periods of comparative steadiness in the price of silver. The principal articles are then examined in detail, and no indication is found that the exports of cotton, seeds, rice, jute, hides, indigo and coffee have been stimulated by the fall in silver.

The views of Mr. Barbour, Mr. O'Connor, and Mr. Waterfield are then briefly stated, and the author's disagreement on some points shortly described. The paper then examines in detail the circumstances of the export trade of wheat, tea, cotton twist, piece goods, and gunny-bags. While attributing the development of the wheat trade in a great measure to the extension of Indian railways, and the cheap

ocean freights, the author disagrees with the contention that the price of wheat has been reduced in Europe by appreciation of gold alone, and thinks that it has been in part brought about by the competition of Indian wheat, which was rendered possible by the favourable circumstances detailed, but which received a fresh stimulus from the fall in the gold value of silver. He ascribes the development of the tea trade to the favourable circumstances in which this industry is placed in India, and to the stimulus given to it by the high gold prices formerly ruling, and thinks that the only effect of the fall in the gold value of silver on it has been to enable the industry to be carried on at the low prices which have resulted from increased production and Chinese competition, and which would otherwise have been unremunerative. While admitting the advantageous conditions which attend the manufacture in India of cotton twist and piece goods and gunny-bags, he explains why he considers these exports have received a stimulus from the fall in the gold value of silver. He then states his general conclusions that, though the export of certain articles has been stimulated, the export trade of India has not on the whole benefited by the fall in the gold value of silver.

6. *On Statigrams, with some suggestions for Greater Uniformity in Comparative Graphics.* By the Rev. J. F. HEYES, M.A., F.C.S., F.R.G.S.

1. The word *diagram* is very loosely used. It is best confined to mathematical and physical science. It is proposed to use the word *statigram* (first put forward in the author's letter in 'Nature' for 1885, p. 597) when graphical statistics of the usual approximate and varying values are being given.

2. The word *graph*, both as a noun and a verb, will be found conveniently short and explicit. Thus a page of figures may be *graphed*, and the resulting *graph* or *graphs* will exhibit a line or curve giving maximum information with minimum trouble. These *graphs* are now becoming well known and popular. They are not necessarily *curves*, so this latter word may thus be given a more restricted and suitable use. As part of the wider science of *Graphics* the whole subject is named *Statigraphy*.

3. It would be convenient to agree upon the use of the co-ordinates. The horizontal line, as far as possible, should, for instance, mark years in preference to the vertical one. In this way the *marriage graph* for the last ten years would be seen to fall in a way corresponding to the diminished rate.

4. It would be convenient to agree to use, whenever possible, *graph paper* (ruled faintly in small squares), with the co-ordinates marked at *standard distances*, say either $\frac{1}{4}$ inch or $\frac{1}{2}$ cm. The half-centimetre distance is much to be preferred, and would, if regularly adopted in international statistics, facilitate comparisons and tend to prevent mistakes. It is also convenient for printed books. In any case the metric system is preferable.

5. In the study of so complex subjects as Geosophy and Sociology all small suggestions which are likely to help are worthy of consideration. These names and the proposed uniformity would, it is believed, help the advancement of science, especially with those who are not mathematicians.

7. *Reasons for a Quinquennial Census.*
By G. B. LONGSTAFF, M.A., M.B., F.R.C.P.

In order to expedite the publication of the results of the census of 1891, as much of the work as possible should be done beforehand; to facilitate this the Bill should be introduced into Parliament in 1889.

The census should be the work of a permanent census sub-department of the General Register Office, which, when not occupied in taking the quinquennial census, would be greatly reduced in numbers; the small permanent staff would, in the intervals, supply all estimates of populations and make special inquiries for Royal Commissions, Select Committees, and Government departments. The work would

thus be better done, and the regular operations of the General Register Office would not be interfered with as at present.

A census is taken every five years by France and Germany, by Queensland and New Zealand. The rapid growth of population in this country and the acknowledged dependence of representation upon population demand that we should have more frequent, and therefore more exact, information.

For instance, the New Local Government Act makes several towns 'county boroughs' on the assumption that on June 1, 1888, they had populations of upwards of 50,000, whereas it is impossible to say, with any approach to certainty, what their populations really were on that day.

The recent inquiry into the immigration of foreign paupers into England to a great extent failed, owing to the want of information less than seven years old.

An exact knowledge of the population is mainly useful as a basis for the calculation of birth-rates and death-rates. In England much money is expended on the calculation and publication of these in the various reports of the Registrar-General and the Medical Officers of Health. These reports are of great value in impressing the need of sanitary improvements on the people and the sanitary authorities, but they lose much of their value from the uncertainty as to the basis upon which such statistics must be built, viz., an exact knowledge of the population. Experience has proved that the official estimates and the census numbers often differ by 10 per cent. in either direction, and sometimes by 15 or even 22 per cent. The Registrar-General himself is ceasing to put any trust in the official estimates of populations, as shown by recent weekly and quarterly reports.

There is reason to believe that, mainly owing to unusually large emigration, the population of the whole United Kingdom was, in April, 1886, or five years after the census, between 400,000 and 500,000 less than the official estimate; an error of $1\frac{1}{4}$ per cent.; in smaller areas the errors are often, proportionately to the whole, very much greater.

These errors in the estimation of the population may involve an error of two or three per thousand in the death-rate, so that elaborate calculations made with a view of correcting errors due to differences in age and sex, and constitution of the population, are thrown away.

The cost of a census being 123,000*l.*, it would not be a great burden upon such a rich country to take one every five years instead of every ten.

The author, therefore, urged the British Association to press upon the Government, by memorial or deputation, the desirability of forming a permanent census sub-department, and taking a census every five years.

TUESDAY, SEPTEMBER 11.

The following Papers and Report were read:—

1. *Leasehold Enfranchisement.* By CHARLES HARRISON.

The author submits this paper on 'Leasehold Enfranchisement' in view of the vital importance which, he considers, the subject bears in relation to the social and economic problems involved in the grave questions of the 'Housing of the Working Classes,' and the reform of the existing Land Laws; and also in view of the many misconceptions entertained by certain sections of the public as to the proposed enfranchisement of leaseholds, being neither more nor less than a communistic violation of freedom of contract, and a socialistic confiscation of the rights of property in private ownership.

The importance of the questions discussed by the author can scarcely be rated too high; it is demonstrated by the fact that a committee of the House of Commons appointed to inquire into the question of Town Holdings in all its various

branches has sat through three consecutive sessions, taking evidence from all parts of the kingdom, and that its labours are still unended.

The author has traced the origin and growth of the system of granting leasehold interests in land through successive stages of legal history; the cause and effect of the Restraining Statutes of Elizabeth; and he has shown that practically the whole of the land on which the metropolis has been developed was formerly held by the Crown, by bodies ecclesiastic and corporate, or by a few of the great historical families, and that it was all but impossible for any private person to acquire a freehold interest in land either in London or its immediate vicinity, prior to the nineteenth century. He argues that as the land was in the hands of these monopolists who could and did dictate such terms as they thought fit, the population, as it increased, was bound to submit to them, and that therefore there could not have been any freedom of contract between contracting parties. Ergo, as there has not been any freedom of contract in the development of the leasehold system, there cannot be any communistic violation of freedom of contract in abolishing it.

The author also deals with the pernicious effect of Private Bill Legislation on property in London, and regards it as one of the main factors in the growth of the present short leasehold system in and around the metropolis.

He points out that between 1700 and 1750 twenty-one separate private Acts of Parliament were passed conferring leasing powers on owners of land in and around the metropolis; and that between 1750 and 1800 no less than fifty-eight further private estate Acts were passed for the same purpose. These Acts were obtained without any discussion as to their public policy. Areas of land, sometimes larger than the old City of London, were dealt with by a single private Act of Parliament; and by this means Parliament enabled tenants for life to deal with settled property in a way unauthorised by the original settlements. Formerly tenants for life could not lease for longer terms than twenty-one years; and it was even considered waste to pull down a house, however ruinous its condition might be, for the purposes of improving or rebuilding it, and no tenant for life had power to do so. In like manner, the bishops and prebends went to Parliament and obtained powers to lease their property, and thus helped to build up the London leasehold system.

The author contrasts the disadvantages of this system of leasing land with the advantages of the freehold fee-farm and chief-rent systems customary in Bath and Bristol and the great majority of towns throughout England, and he says that what is good for all England must be good for the metropolis.

He states the machinery proposed to be put in motion for the enfranchisement of leaseholds, and explains that full compensation is to be paid to the ground landlord for the reversion dependent on the expiration of the lease. The 12 and 13 Vict. c. 105 (Ireland) conferred upon lessees the right of acquiring the fee-simple of the property leased by them, provided the lease is perpetually renewable. The Conveyancing Act of 1881 gives power to a tenant to purchase the reversion where no money rent is reserved; and in the same way it is proposed by the Leaseholds Enfranchisement Bill to give power to a tenant to purchase the reversion where a money rent is reserved, provided the tenant has an unexpired term of a certain number of years.

The author strongly denounces the evils and hardships of the London leasehold system, and advocates the freehold system as being the most perfect of all known systems of land tenure; or, in the alternative, the fee-farm or rent-charge system, such as is now, and has been for centuries past, customary in the city of Bath and the adjoining city of Bristol.

2. *Report of the Committee for continuing the Inquiries relating to the Teaching of Science in Elementary Schools.*—See Reports, p. 164.

3. *The Industrial Education of Women abroad and at home.*
By E. J. WATHERSTON.

4. *Irishwomen's Industries.* By Miss HELEN BLACKBURN.

The industries at present existing amongst women in Ireland are eminently cottage industries. Cottage industries, not requiring large capital, are peculiarly fitted to the condition of the country ; moreover, they suit the tastes of the people and the scattered nature of their dwellings. Ireland, therefore, presents a specially favourable field for such industries ; but to preserve those already existing, and to develop them further, much is needed in the way of skilled direction and organisation of trade arrangements.

The years of the famine of 1846-48 first drew public attention in any marked degree to the capacities of Irishwomen's fingers, and the results the needle produced in those calamitous days were truly astonishing. Of the numerous centres of work then organised, many have long wholly disappeared, while of those that remain the most firmly established are in the North, where the work is in the hands of large commercial firms, and thus secure of a permanent market.

It is true that in Belfast, the chief factory town of Ireland, the majority of women workers are employed in the mills, while box-making and tobacco factories, and a few other lesser industries, employ some ; nevertheless, of the 4,000 women estimated to be employed in shirt and collar making, a quarter are estimated to do the work at home, and in and round Londonderry, which is the centre of the shirt-making trade, a larger proportion. Hemstitching handkerchiefs is stated to employ 20,000 women, and these, together with numbers employed in sewed muslin and embroidery, bring work into every cottage over the greater part of Ulster.

But in the rest of Ireland the centres now at work are too dependent on private effort. They have mostly been started since the years of distress of 1880-81 ; thus, to name a few, the knitting industries of Valencia Island, Athea, and the Rosses were started in 1880, 1883, and 1884. The revival going forward in the lace-work of Munster dates from the Cork Exhibition of 1883, when the Convent Lace Schools awoke to the necessity of improvement in design, and the revival manifested itself with marked success in the renaissance of Limerick lace. The revival of pillow lace-making in Mayo ; the Clonmel Industrial Association ; the straw bottle-envelope factory in Galway ; and the Association for Promoting Silk Cultivation in the South of Ireland,—all have arisen within the last four years.

To tell of what has been done is to remind ourselves of how much more is needed to be done to make these openings of lasting duration. The efforts already made by various ladies have overcome some of the initial difficulties, chief of which is the lack of precision and punctuality. These ladies have set the women on the way to habits of industry and cleanliness ; but the numbers employed must remain comparatively few until the industries thus laboriously started are made independent of the precariousness of private endeavour. For this they need permanent teaching power, organised channels of distribution, means of knowing how to adapt their work to the demands of the market, as well as how to get it there. Nor do these needs apply only to the cottage centres. The jute and brush factories of Galway, which already employ many women—partly in the factory, partly in work done at home—might employ more. Glove-making, once a well-marked skilled trade for women in Ireland, is susceptible of revival ; jam-making, now on the increase, is a trade in which women are chiefly employed, and which brings with it the correlative industry of fruit-growing. The cottagers of the wilds of Galway are beginning to find out that there is an outside demand for the home-spun, home-dyed flannels characteristic of the district.

The new City of Dublin Technical Schools admit women, so does the Belfast School of Science and Technology. The Munster Dairy School in Cork and the Glasnevin Dairy School, co. Dublin, are doing good work. But these are not enough ; they may teach teachers, but classes are wanted everywhere. Here the movement towards technical teaching in the convent schools is worthy of note ; nothing can better show that there is a healthy movement at work than the way in which the Convents of the Sisters of Mercy are beginning to start cookery and dairy classes. The importance of this may be realised when we reflect that there is not a town

of any size in Ireland in which these earnest and energetic women have not a school.

Even in respect to butter-making, the capabilities of the country have never been properly drawn out, much less in the cultivation of early poultry, early flowers, and early vegetables. Rapid transit once arranged, an immense and unsuspected amount of produce now running to waste might be utilised, and garden ground now idle turned to profit.

We often hear of the hopelessness of cottage work as against machinery, but the iron hand can never come up with the skilled hand of nerve and muscle in taste, delicacy, and variety of workmanship.* The three urgent needs of Ireland to-day, to enable its domestic industries to flourish, are:—

1. Technical teaching power, for the exercise of which surplus workhouses and convent schools afford facilities.
2. Organised means of distribution, such as the Home Industries' Association in Dublin is endeavouring to establish.
3. Arrangements for rapid transit of perishable produce. These three points demand the careful consideration of all who wish to see possibilities of home industry opened out to Irishwomen of every rank and degree.

5. *Education : a Chapter of Economics.* By T. W. DUNN, M.A.

1. There are no technical schools in Bath. The educational work does not differ from that of most places. Need here, as elsewhere, of ladders to help promising boys from primary to secondary schools. The bearing of such an arrangement on economics. 'Tools to the hands of him that can use them.'

2. The subject is General—the Influence of Education on the Production of Wealth. The Theory of Education is still in the stage of discussion in which inquirers differ.

3. Of the elements of production, labour, or the labourer, alone directly concerned.

4. Wider sense of labour: 'hands,' 'managers.'

5. Tendency to undue subordination of general to technical education. Mischievous consequence in schools and in industries.

6. What the labourer has in common with other labourers is due to general, what he has in difference to technical, training.

7. Industrial organisation *based* upon what labourers have in common. First a man, then a workman.

8. Illustration. Fishermen, single and co-operative.

9. How far increase of production due to improved character and skill. Vast improvement to be expected from good faith in workmen and a sense of common interest.

10. Men of science propound lopsided theories of education. Philosopher or man of general culture alone to legislate.

11. Children work for work's sake, or *play*; boys work in order that they may work, or *learn*; men work that they may get, or *produce*.

12. Primary schools teach assiduity, or patient persistence in routine and mutual concession or the social faculty. Immense value of these qualities. These schools repress energy and are unfavourable to the artistic spirit. Play, or work for its own sake, and the spirit of play in learning, alone teaches the passion for excellence. This is seen in the fine arts. Hence the importance attached to organised games in secondary schools. Hence, too, the radical unfitness of utilitarian subjects for education and the necessity of distinguishing between education and apprenticeship. Digging and gymnastics, land surveying and mathematics. 'Commercial certificates.'

13. The sciences as subjects of school education. Language and literature the reservoir of traditional and accumulative culture and knowledge, as well as the instrument and cement of social organisation and co-operation.

14. Industrial order, a picnic from which we all tend to draw out only what we put in.

6. *L'organisation et la statistique de l'enseignement technique secondaire en Italie.* By Signor BONGHI.

Je regrette, messieurs, de devoir vous communiquer ces quelques notes sur l'organisation et la statistique de l'enseignement technique secondaire en Italie dans une langue qui n'est ni la vôtre ni la mienne ; mais j'y suis forcé, ne sachant pas prononcer assez bien la vôtre, et la mienne n'étant pas assez généralement comprise. Mais puisqu'il en est ainsi, je n'aurai garde de trop compter sur votre patience ; et je me limiterai à toucher seulement les points les plus importants de mon sujet, pour que vous ayez une juste idée de l'état de cette partie de l'instruction publique dans mon pays, et je laisserai de côté tout ce qui peut s'y rattacher dans l'enseignement élémentaire et dans l'enseignement supérieur, ainsi que les instituts nautiques.

L'idée d'écrire sur ce sujet le mémoire, dont j'extrais les notes que je vous lis, m'est venue l'année passée en assistant à Manchester aux conférences et discussions de la section économique de cette Association. On y a beaucoup parlé d'instruction technique, et dans cette occasion l'Italie a été très souvent citée par les orateurs, qui reprochaient au gouvernement anglais de n'avoir rien fait jusqu'à présent pour l'instruction technique, ni en forme de subside ni en forme d'organisation obligatoire d'écoles appropriées comme il a pourtant fait pour l'instruction élémentaire. On paraissait croire que ce qui manquait ici se trouvât en Italie parfaitement organisé et développé. Or, ceci n'est pas tout à fait vrai.

Nous avons en Italie un code d'instruction publique qui date de 1859. Il n'a pas été discuté et voté par les chambres, mais conçu et publié par le ministère du temps qui en avait eu ou croyait d'en avoir eu le pouvoir. Or, dans ce code on règle l'instruction qu'on y appelle technique, comme les autres. On y établit que l'instruction technique soit donnée dans une école technique—1^{er} degré—et dans un institut technique—2^d degré, et aux deux degrés en trois ans. La dépense en est partagée en différentes proportions entre l'Etat, la commune et la province ; et le gouvernement a le droit de fonder l'une ou l'autre de ces institutions scolastiques dans les communes qui se trouvent en certaines conditions. La loi, pourtant, n'a pas été parfaitement exécutée, par des raisons que je dois omettre ici ; et le fait est, qu'il y a actuellement en Italie 141 écoles techniques gouvernementales, avec 13 mille élèves presque, et 49 instituts gouvernementaux avec 5,500 élèves. Mais en outre il y a 102 écoles techniques communales avec 8,400 élèves, et 18 instituts provinciaux avec 1,200 élèves. Ce sont des écoles ou des instituts que les communes ou les provinces soutiennent à leurs frais, sans y être obligées par la loi. Je donne les chiffres de 1886-87, car il n'y a pas de statistique plus récente.

Ainsi il paraîtrait qu'on soit fondé à croire que l'organisation de l'instruction technique est parfaitement développée en Italie, et que les orateurs qui en proposaient l'exemple au gouvernement anglais avaient parfaitement raison. Mais au contraire le fait est, que la loi de 1859, qui a établi les institutions dont je viens de vous parler, a appelé technique une instruction qui ne l'est pas, et qui ne s'appelle ainsi ni chez vous ni partout ailleurs. L'instruction qu'elle a appelée technique est plutôt une instruction professionnelle, si vous voulez appeler ainsi une instruction qui n'est pas classique, c'est-à-dire qui n'apprend ni le grec ni le latin, qui met à leur place deux langages modernes, et qui a pour but de fournir des aptitudes et des connaissances nécessaires à tous ceux qui veulent ou doivent se contenter d'emplois ou de professions de moindre valeur et importance que celles auxquelles on arrive par les études supérieures ou universitaires. Ce but nous le trouvons à présent très imparfaitement atteint par les deux institutions de la loi de 1859 ; et rien ne nous paraît plus urgent que de les transformer.

Ainsi quant à ces deux institutions, nous ne pouvons être proposés pour modèle. L'instruction que nous appelons technique ne mérite ce nom qu'exceptionnellement dans un très petit nombre d'instituts, où une des sections dans lesquelles les instituts se partagent s'est développée dans un sens vraiment technique. Pour tout le reste, l'instruction que la loi a appelée technique n'est qu'une instruction professionnelle qui ne nous paraît pas à nous-mêmes assez bonne ou utilement distribuée.

L'école et l'institut, dont je vous ai parlé, sont gouvernés par le ministère de l'instruction publique, mais pendant un certain temps c'est le ministère de l'agriculture et du commerce qui les a gouvernés. Le changement de dépendance vous prouve ce que je viens de vous dire sur leur caractère. Parce qu'elles se nommaient techniques, le ministère de l'agriculture et du commerce les réclamait ; parce qu'au fond elles ne le sont pas, le ministère de l'instruction publique les a reprises. Une fois que le ministère de l'agriculture et du commerce en a été privé, il a développé, plus vigoureusement qu'il n'avait fait jusqu'alors, un enseignement qui est vraiment technique en dehors de l'école et de l'institut, improprement ainsi dits. Si l'on croyait pourtant que la distinction de compétence entre les deux ministères soit tout à fait claire et parfaite, et qu'il n'arrive pas qu'il y ait des doubles emplois dans les créations scolastiques de l'un et de l'autre, on se tromperait. Je crois que, dans l'intérêt du budget et d'une organisation simple et forte, il vaut mieux que tout ce qui est instruction publique, de quelque genre que ce soit, jusqu'où on croit nécessaire que l'Etat s'en mêle, dépende d'un seul ministère. C'est ce que m'a appris l'expérience de mon pays.

En attendant, voici comment le ministère de l'agriculture et du commerce a développé une instruction vraiment technique. Il en distingue trois sortes : l'instruction agricole, l'instruction d'arts et métiers, l'instruction d'art appliqué à l'industrie.

Seulement la première est réglée par une loi, très récente d'ailleurs, car elle date de 1885.

Cette loi établit trois genres d'écoles agricoles : écoles pratiques générales, écoles pratiques spéciales et stations agraires. Dans les dernières on n'enseigne pas : le directeur expérimente, essaye, étudie, donne des conseils. Dans les écoles pratiques on apprend ou la science et l'art de la cultivation de la terre en général ou surtout la science et l'art d'une culture particulière. Le gouvernement peut en établir une par province. L'Italie pourrait en avoir 74 : elle en a 27, mais pas toutes sur le même type ni du même coût. Le nombre des élèves qui les ont fréquentées dans l'année 1886-87, et qui vivent la plupart dans des collèges annexés à l'école, n'a pas surpassé le millier. La dépense de l'école et du collège est partagée entre l'Etat, la commune et la province.

Passons aux écoles d'arts et métiers et d'art appliqué à l'industrie. Elles ne sont pas réglées par une loi, comme je viens de le dire. Le gouvernement en a présenté une, mais elle n'a pas été votée et ne sera pas votée de sitôt. Jusqu'à présent ces écoles ont été créées par acte du pouvoir exécutif, résultat ou de la pensée même du ministre ou de l'influence d'un membre du parlement ou de l'initiative de quelques citoyens. Le parlement s'y est associé en accordant dans le vote annuel du budget les sommes que le gouvernement, par une convention avec la commune ou la province où l'école se fondait, avait mises à sa charge.

De cette manière on a jusqu'à présent fondé en Italie 144 écoles de différents types et dénominations, et ayant pour objet différents arts, avec des cours de jour ou de soir, pour hommes et pour femmes. Elles sont fréquentées par presque 20,000 élèves. On fonde de pareilles écoles tous les ans ; ainsi le nombre en va toujours augmentant.

Ces écoles, qui ont été fondées en différents temps, mais toutes depuis trop peu de temps pour en apprécier les bienfaits, ont pourtant dû exercer quelque influence dans ce réveil des industries artistiques qui s'est vu en Italie pendant les dernières quinze années, et que vous avez pu apprécier et vous avez apprécié avec tant de bienveillance à l'Exposition Italienne à Londres. Mais il faut ajouter que ce réveil est dû aussi en grande partie au réveil national, par lequel chaque citoyen italien et par conséquence chaque ouvrier a senti renaître dans son esprit le goût de l'ancien art de son pays, et diminuer le goût de l'imitation d'un art étranger, surtout de l'art français. L'ouvrier italien s'est trouvé plus hautement, plus profondément inspiré par l'art exquis, d'une si suprême élégance et pureté, du quinzième et du seizième siècle. Le développement de l'école technique a été plutôt l'effet que la source de ce mouvement ; mais certainement elle l'a aidé et elle l'aide. C'est tout ce qu'on peut ou doit en attendre.

7. *Agricultural Education.* By Professor JAMES LONG.

Agricultural prosperity will return with the advance of agricultural education.
The farmer's son of to-day trained at a commercial school.

The son of the Continental farmer has a choice of numerous agricultural schools of different grades.

The agricultural classes deficient in their knowledge of the principles of agriculture.

Admitted that agricultural education requires State aid: what does the present system do under the Science and Art Department?

6,578 students at 332 schools.

4,266 students examined and 3,583 passed, earning a grant of 3,123*l*.

The three years' course for the associateship chiefly includes a knowledge of certain sciences—chemistry, physics, astronomy, biology, geology, mineralogy, mechanics—the agricultural course only coming in one term of the third year.

Astonishment of the authorities that only one student has attempted to take it.

In the last year, eight teachers had attended the thirty-eight weeks' course, and thirty-one the three weeks' course, at a cost of 907*l*.

Suggestion as to a central normal school and farm.

The children in rural schools to have the option of two extra subjects, of which agriculture should be one.

In particular districts special subjects applicable to those districts should be more fully taught, such as dairying, fruit-growing, hop-growing, bee-keeping.

Subjects under the head of agriculture, taught at the rural schools, should be most comprehensive, although elementary.

Weekly night-schools for the pupils who have left the rural schools.

Free scholarships to district schools of agriculture.

Establishment of five district agricultural schools for England and Wales. Each to have, in addition, a special course; two for dairying, one for horticulture (including fruit-growing and preserving, and market gardening); one for biology and botany, and one for forestry.

Free scholarships from the district to the central agricultural school.

Exhibitions from the central school, to enable students to travel abroad.

Travelling lecturers.

8. *Economy in Education and in Writing.* By ELIZAK PITMAN.

A million pounds yearly are wasted by the present method of teaching reading in our elementary schools, which might be saved by the use of phonetic reading books; and a hundred million hours yearly are wasted in writing by those who speak the English language.

There are five million children in the common schools of the country. Their first occupation is to learn to read, and they spend, at the lowest reckoning, eight hours per week in gaining a certain amount of reading power during the first four years of their school life. An equal degree of proficiency might be gained by using phonetically printed books during the first *two* years' schooling, and by reading in the present books afterwards.

The annual cost of our elementary schools is five million pounds. The proportion of this sum spent in teaching reading is a little more than one-third. From seven to ten hours, according to the Education Code, are required to be thus occupied out of a total attendance of twenty hours per week. Say that on an average eight hours per week are devoted to reading. The cost of teaching reading alone to these five million children is, therefore, two million pounds. One half of this sum would be saved by the use of an alphabet containing a letter for each sound in the language. As reading is now taught, the sound or pronunciation of every word has to be learned independently of the names of the letters that compose it; and generally in spite of the names or sounds of the letters. But by the use of letters that make up the sound of a word certainty and celerity in the art of

reading take the place of doubt and difficulty; and what is now an irksome task to both teacher and pupil would become a delightful pastime.

Our present style of writing is 'cumbersome in the last degree, and unworthy of these days of invention.' By the use of phonetic shorthand the time spent in writing is reduced to one-fourth, and the writing is as legible as longhand. On a very moderate computation there are a million persons out of the hundred millions who speak the English language that occupy, on an average, one hour a day in writing, or three hundred hours in the working days of a year. This amounts to three hundred million hours in the course of a year. Three-fourths, or say one-third, of this time would be saved by the use of shorthand. Reckoning twelve hours as a working day, above twenty-seven thousand years are annually lost to the world by our slow and tedious method of writing.

The phonetic alphabet for teaching reading and the shorthand alphabet were then exhibited.

WEDNESDAY, SEPTEMBER 12.

The following Papers were read:—

1. *The Malthusian Theory.* By EDWIN CHADWICK, C.B.

When Malthus wrote his book on the 'Pressure of Population on the Means of Subsistence,' the population of England was ten millions, and in the manufacturing districts the wages were low, and the prices of provisions were high. Take Lancashire: the wages given at the commencement of the cotton manufactures were not more than five shillings per head of the cotton mill workers, man, woman, and child; that is to say, if there were three workers in a cottage, the aggregate wages they received were not more than fifteen shillings per week. In agriculture, in Scotland, Adam Smith states that the wages for adult workers at that period were eightpence a day. The wages now in Lancashire average seventeen shillings per head of the mill workers, and in a cottage of three—man, woman, and child—the wages may amount to 2*l.* 10*s.* per week. The agricultural wages in the highly cultivated districts in Scotland are now about 1*l.* per week for the man, 6*s.* for the woman, and 4*s.* for the boy, besides a good cottage and other advantages. Now it may be stated as an economical principle, that the fact of an artisan being employed at wages denotes that over and above his own means of subsistence, he earns enough to yield a profit to the capitalist who employs him, and the continued advance of wages denotes a continued diminution of the pressure of that population on the means of subsistence. And this has been going on, as in Lancashire, with the increasing introduction of labour-saving machinery.

At the beginning of the century, the spinning of a pound of cotton cost 1*s.*; it now costs $\frac{1}{2}$ *d.*, and there is now paid the highest amount of wages with the lowest cost of production of any in Europe. The population in Lancashire has increased from half a million to three millions and a half, and it is going on increasing; whilst the death rate has been considerably reduced. A Cabinet minister is reported to have stated in a recent speech: 'The vast questions connected with population have to be considered. It is growing at a rate which I do not like to cite, but you know Professor Huxley's estimate. Are we taking measures to deal with that population in an intelligent and far-sighted way? I venture to think that we are taking very few precautions, if any. And when you come to think what that question of population involves, you must see that it is one which will force itself on our attention in a very unmistakable way before long. In the first place, it forces on us the great question of the land of this country, which remains limited, while the population knows no limit to expansion.' This quietly assumes the limited cost of production, and the limited amount of the production. Sir Robert Kane, in his work on the 'Industrial Resources of Ireland,' declares that the cultivable land of that country is capable of a threefold

production greater than is now obtained from it, but that the landlords of Ireland are generally incompetent from want of skill to obtain it by labour-saving machinery. In England, it is in evidence that the labour-saving machinery in use in agriculture is not so productive by one-half, as the like machinery in use in the United States. And yet in England, the yield, say, of wheat, is double what it is in France or in Germany, and according to the examinations of the late Mr. Jenkins, the owner of land in *petite culture* works twice as hard for this reduced produce and for half the wages of a well-paid labourer in England. In Germany, the produce of every sort is one-half what it is in England. In England, however, more than half the land that would be largely improved for profitable production by drainage, is as yet undrained. Of the possible augmentation of production in England by high culture it may be stated, that whilst the common production is as one, the high production of market garden culture is as three and a half, whilst the liquefied manure culture, as set forth by De Candolle as the future of agriculture, by giving food and water at the same time, is as five. And yet in the metropolis, prepared plans for the distribution of fresh sewage have been set aside, and the fresh sewage which would yield the milk of 200,000 cows, is thrown into the river Thames in a condition of putridity, to its gross pollution.

It may be mentioned as an incident in analogy with the course of population in Lancashire, that in Norfolk, where the greatest amount of labour-saving machinery has yet been introduced, the agricultural population appears rather to have increased.

Now, in regard to the doctrine of the assumed natural check of pestilence to increase of population. In the investigation on the subject of Poor Law Relief, I found that in the healthy agricultural districts the intervals of births, where the mothers suckled their own children, was about two years, and that where there was a family of eight children, the eldest would be sixteen years of age, the second fourteen, and the third twelve, capable of earning their own subsistence. In the depressed districts, on the other hand—the slums of the metropolis, more heavily ravaged by epidemics—the intervals of births were only one year, the conceptions taking place immediately after each birth. Extended experience shows that, except in such extraordinary pestilences as the Black Death, ordinary pestilences do not diminish population, but only leave it weakened. This may be exemplified from India and elsewhere. As health and the duration of life is advanced, the proportion of births appears to be rather diminished, as with the well-to-do classes. To sum up, it is shown that where wages increase, the pressure of population on the means of subsistence is diminished; that, instead of the cost of the production of land being fixed, it is generally reducible largely by science and machinery, whilst the amount of produce may be everywhere augmented, and that mostly in the regions of *petite culture*; that, instead of pestilence being the natural check to population, it does not diminish that pressure, but serves to weaken population and diminish its productive power, and increase the pressure of population on the means of subsistence.

I cannot descry the limits of a further advance of prosperity in this country with a further increase of population. I expect it will be found with a fifth or a fourth more of population. And then as to external relief. It is declared by a French authority that only one-sixth part is yet inhabited of the cultivable parts of the world. Mr. Justice Cunningham declares that in India 'there are still 79 millions of cultivable acres not utilised, and the rate of produce might be increased so as to provide for an additional population of 400 millions.' Mr. Bence Jones succeeded to an estate in Ireland when the wages were 3*d.* a day and the rental 10*s.* an acre. He advanced the wages to 2*s.* a day, and the valued rental to 40*s.* per acre, and was proceeding to advance still further at the time of his death. But scarcely an instance was known of a similar advance in all Ireland. In France and Germany a similar augmentation of production is proved to be practicable.

3. *Amendments founded on Experiences submitted for the Local Government Bill.* By EDWIN CHADWICK, C.B.

Extended Functions of the County Councils.—In great part the local administrations of all sorts are now occupied by members who are concerned in contracts for supplies. If the Committee on the Poor Law Relief had been carried further, this might have been shown in evidence. Dr. Mouat might have been called as a witness, and he would have shown, in respect to the supplies for the metropolis, that he had examined them twice, and he might have given in tables showing the extraordinary variations in the prices of supplies, and have given reasons for the conclusion that these variations were mainly variations in jobbing commonly at the expense of qualities. Of the children under the administration of the poor-law, only one-third are in the large district schools; two-thirds of them are kept under an inferior administration in the union houses, where they are mixed up and made familiar with the ways of old and depraved paupers. But the consents of the guardians are necessary to the creation of the superior district establishments freed from such influences, and that are more economical as well as superior in results. It is perfectly well known that the refusal to the formation of the district institutions is based on the interest in the retention of the patronage of supplies. To counteract this, and also for superior economy, it is proposed as an amendment that the County Boards should be charged with the exclusive power of making contracts for supplies of provisions and materials for the whole of the public institutions within the county. This would give the benefit of a superior intendence, better qualities of supplies, and the economy of wholesale prices. It would give a means of distributing employment in the different institutions—clothing in one, bakeries, &c., in others. The superior administration in Paris, where the whole of the supplies for the hospitals and other public institutions are under one intendence, and well organised intendence, may serve as a contrast with the conditions found by Dr. Mouat, and flagrantly displayed in the divers vestries of London. But this provision, shifting the contracts, would largely influence the new local administrations throughout the country. It would tend to clear them effectively of the jobbing interests, and to give a new and pure start to the new local administration.

Remedies against Jobbing Appointments.—One great vice of the present local administration is the inveterate habit of jobbing the appointments. This is in distinct contravention of early principles of securities provided in poor-law administration against this evil, but which have extensively fallen through. The remedy available for the local appointments is the principle of testing them by competitive examinations, and this remedy is now sought to be introduced in the United States. It has there been applied to about one-fifth of the public appointments, and has worked so well that it is contended for general application. The Honourable Mr. Seth Low, late Mayor of Brooklyn, states that it has been applied there not only to policemen, but to labourers who are officially employed. The extension of the practice to high officers is now being contended for in France as a remedy for the great political corruption there. An example of the application of the principle may be taken from the County Grand Juries of Ireland. At Dublin competitive examinations are conducted by the Scientific Board of Works, and on any vacancy occurring in the county surveyorships some half-dozen of the leading competitors are presented to the grand juries for their choice of one. A scientific administration is thus secured for the roads of Ireland. Field-Marshal Sir John Burgoyne, who served there, has shown that, under this administration, there is a saving at least of one horse out of five, as compared with the roads as commonly administered in England. In Ireland the cost of maintaining the superior road is 20*l.* a mile per annum. In England the cost of the main road per annum is as much as 38*l.* per mile, with the exception of some parts where a consolidation has been effected by Mr. Thomas Codrington, the scientific Inspector of the Local Government Board. It is submitted as an amendment that with the exception of those who have already undergone competitive examination, such as the Royal Engineers and others,

future local appointments shall be made from successful competitors in examinations by the Civil Service Commissioners for the Empire.

Reduction of Electoral Expenses.—As the Local Government Bill now stands, with the procedure for the elections at polling-booths, the same as in the boroughs, it will frequently involve expenses as great as those of elections to Parliament, and will exclude many fitting candidates. The results at the elections by the polls for the School Board of London have been such as to exclude the most fitting specialists in education, and to admit grossly ignorant and ill-qualified persons. The expense to the ratepayers of this system, which gives the returns generally to minorities and to ignorance or to jobbery, it will be found would suffice to defray the expenses of a superior board of specialists giving their undivided and constant attention in harmony with the latest improved educational principles, whose value would receive general recognition from Parliament as well as from the public at large.

Out of 1,398 contested elections for guardians which took place in 1874-75, it appeared from a return to the House of Lords that there were only seven complaints, scarcely more than 1 per cent. of the electors, of which four of the complaints were adjudged to be well founded. On comparison of these results with the election of members of Parliament, the complaints of false returns on account of bribery, corruption, or intimidation at each dissolution were upwards of 20 per cent. of the elections, and it was notorious that they would have been far more numerous but for the enormous expense of prosecuting the petitions. In the case of the house-to-house collection of votes the petitions are made and examined and determined gratis. It is assumed that the ballot is incompatible with the house-to-house collection of voting papers. This is a fallacy. House-to-house collections of ballots for candidates are practised by charitable associations. An open envelope containing a balloting paper is transmitted by post to the elector, who takes out the paper, marks his candidate, returns the paper into the envelope, closes it, and sends it back to the returning officer under some safe method, which might be by postal delivery and collection under securities of registered letters.

Let it be considered what is the practice of elections in the great civil business of the country; what would be their stability if, as in political life, they were made dependent on the decisions of the hundreds who may be got to meetings, as against the thousands who cannot be got to attend them, but whose voices are brought to the poll by the house-to-house collection of votes as proxies. The plurality of voting is objected to, but, in respect to landed property, the fact is omitted to be observed that on the average two-thirds of rent represents capital in buildings, steadings, roads, hedges, &c. Now where is any objection raised to plurality of votes proportioned to holdings of shares in all commercial institutions? It is proposed that at all events candidates shall be allowed to call for a preliminary test ballot as by way of a show of hands, or by show of collected papers, to be distributed by the post, in such form as the Local Government shall regulate, containing a balloting paper, such as are in use by private societies. All parties would frequently abide by this preliminary test, which need not cost more than a registered letter.

A Completed Imperial Police Force.—In local agricultural associations the eligibility of an imperial police force is fully recognised exclusively of the grounds of its adoption as a great reserve military force, and as a means of repression without bloodshed, and as an economy of military force which has been fully explained.

4. *The Vital and Commercial Statistics of Bath.* By F. NORFOLK.

5. *Old Age and Sickness Assurance for the Mercantile and Professional Classes.* By F. NORFOLK.

SECTION G.—MECHANICAL SCIENCE.

PRESIDENT OF THE SECTION—W. H. PREECE, F.R.S., M.Inst.C.E.

THURSDAY, SEPTEMBER 6.

The PRESIDENT delivered the following Address:—

'CANST thou send lightnings, that they may go, and say unto thee, Here we are?' were pregnant words addressed to Job unknown centuries ago. They express the first recorded idea in history of the potentiality of electricity to minister to the wants of mankind. From Job to Franklin is a long swing in the pendulum of time. It was not until that American philosopher brought down atmospheric electricity by his kite-string in 1747, and showed that we could lead it where we willed, that we were able to answer the question addressed to the ancient patriarch. Nearly another century elapsed before this mysterious power of Nature was fairly conquered. It has been during this generation, and during the life of the British Association, that electricity has been usefully employed; and it is because I have taken a subordinate position in inaugurating nearly all of its practical applications, that I venture to make the developments of them the text of my address to this section.

People are singularly callous in matters affecting their own personal safety; they will not believe in mysteries, and they ridicule or condemn that which they do not understand. The Church itself set its face against Franklin's 'impious' theories, and he was laughed to scorn by Europe's scientific sons; and even now, though commissions composed of the ablest men of the land have sat and reported on Franklin's work in England, France, and nearly every civilised nation, the public generally remains not only ignorant of the use of lightning conductors, but absolutely indifferent to their erection, and, if they are erected, certainly careless of their proper maintenance. I found in a church not very far from here the conductor leaded into a tombstone, and in a neighbouring cathedral the conductor only a few inches in the ground, so that I could draw it out with my hand. Although I called the attention of the proper authorities to the absolute danger of the state of affairs, they remained in the same condition for years.

Wren's beautiful steeple in Fleet Street, St. Bride's, was well-nigh destroyed by lightning in 1764. A lightning rod was fixed, but so imperfectly that it was again struck. In July last (1887) it was damaged because the conductor had been neglected, and had lost its efficiency.

As long as points remain points, as long as conductors remain conductors, as long as the rods make proper connection with the earth, lightning protectors will protect; but if points are allowed to be fused, or to corrode away; if bad joints or faulty connections are allowed to remain; if bad earths, or no earths, exist, protectors cease to protect; and they will become absolute sources of danger. Lightning conductors, if properly erected, duly maintained, and periodically inspected, are an absolute source of safety; but if erected by the village blacksmith, maintained by the economical churchwarden, and never inspected at all, a loud report will some day be heard, and the beautiful steeple will convert the churchyard into a new geological formation.

We have not yet acquired that mental confidence in the accuracy of the laws that guide our procedure in protecting buildings from the effects of atmospheric electrical discharges which characterises most of the practical applications of electricity. Some of our cherished principles have only very recently received a rough shaking from the lips of Professor Oliver Lodge, F.R.S., who, however, has supported his brilliant experiments by rather fanciful speculation, and whose revolutionary conclusions are scarcely the logical deduction from his novel premises. The whole subject is going to be thoroughly discussed at this meeting.

We are now obtaining much valuable information about the nature of lightning from photography. We learn that it does not, as a rule, take that zigzag course conventionally used to represent a flash on canvas. Its course is much more erratic and sinuous, its construction more complicated, and pictures have been obtained of *dark* flashes whose *raison d'être* has not yet been satisfactorily accounted for. The network of telegraph wires all over the country is peculiarly subject to the effects of atmospheric electricity, but we have completely mastered the vagaries of lightning discharges in our apparatus and cables. Accidents are now very few and far between.

The art of transmitting intelligence to a distance beyond the reach of the ear and the eye, by the instantaneous effects of electricity, had been the dream of the philosopher for nearly a century, when in 1837 it was rendered a practical success by the commercial and far-sighted energy of Cooke, and the scientific knowledge and inventive genius of Wheatstone. The metallic arc of Galvani (1790) and the developments of Volta (1796) had been so far improved that currents could be generated of any strength, the law of Ohm (1828) had shown how they could be transmitted to any distances, the deflection of the magnetic needle by Oersted in 1819, and the formation of an electro-magnet by Ampère and Sturgeon, and the attraction of its armature had indicated how those currents could be rendered visible as well as audible.

Cooke and Wheatstone in 1837 utilised the deflection of the needle to the right and the left to form an alphabet. Morse used the attraction of the armature of an electro-magnet to raise a metal style to impress or emboss moving paper with visible dots and dashes. Steinheil imprinted dots in ink on the different sides of a line on paper, and also struck two bells of different sound to affect the ear. Bréguet reproduced in miniature the actual movements of the semaphore then so much in use in France; while others rendered practical the favourite idea of moving an indicator around a dial, on which the alphabet and the numerals were printed, and causing it to dwell against the symbol to be read—the A, B, C instrument of Wheatstone in England, and of Siemens in Germany. Wheatstone conceived the notion of printing the actual letters of the alphabet in bold Roman type on paper—a plan which was made a perfect success by Hughes in 1854.

At the present moment the needle system of Cooke and Wheatstone, as well as the A, B, C dial telegraph, are very largely used in England on our railways and in our smaller post offices. The Morse recorder and the Hughes type-printer are universally used on the Continent; while in America the dot and dash alphabet of Morse is impressed on the consciousness through the ear by the sound of the moving armature striking against the stops that limit its motion. In our larger and busier offices the Morse sounder and the bell system, as perfected by Bright, are largely used, while the press of this country is supplied with news which is recorded on paper by ink dots and dashes at a speed that is almost fabulous.

Sir William Thomson's mirror—the most delicate form of the needle system—where the vibratory motions of an imponderable ray of light convey words to the reader, and his recorder, where the wavy motion of a line of ink spirted on paper by the frictionless repulsion of electricity performs the same function, are exclusively employed on our long submarine cables.

Hakewell in 1848 showed how it was possible to reproduce facsimiles of handwriting and of drawing at a distance, and in 1879 E. A. Cowper reproduced one's own handwriting, the moving pen at one station so controlling the currents flowing on the line wire that they caused a similar pen to make similar motions at the other distant station. Neither of these plans, the former beautifully developed by

Caselli and d'Arlincourt, and the latter improved by Robertson and Elisha Gray, has yet reached the practical stage.

The perfection of telegraphy has been attained by that chief marvel of this electrical age—the speaking telephone of Graham Bell. The reproduction of the human voice at a distance, restricted only by geographical limits, seems to have reached the confines of human ingenuity; and though wild enthusiasts have dreamt of reproducing objects abroad visible to the naked eye at home, no one at the present moment can say that such a thing is possible, while in face of the wonders that have been done no one dare say that it is impossible.

The commercial business of telegraphy, when our thoughts and wishes, orders and wants, could be transmitted for money, was inaugurated in this country by the establishment of the Electric Telegraph Company in 1846, and until 1870 it remained in the hands of private enterprise, when it was purchased by the Government, and placed under the sole control of the Postmaster-General. It has been the fashion to decry the terms of purchase of the various undertakings then at work by those who have not understood the question, and by those who, being politically opposed to the Government in power at the time, saw all their acts, not only through a glass darkly, but through a reversing lens. A business producing 550,000*l.* per annum was bought at twenty years' purchase, and that business has now increased to 2,000,000*l.* per annum. 6,000,000 messages per annum have increased to 53,400,000.

Every head post office has been made a telegraph office, every village of any size has its wire; messages which used to cost 12*s.* 6*d.* are now sent for 6*d.*; a tariff which was vexatious from its unfair variation is now uniform over the United Kingdom, and no one can justly complain of error or delay in the transmission of their messages. Silly complaints are sometimes inserted in the press, of errors which the most elementary knowledge of the Morse alphabet would detect, and little credit is given to the fact that the most perfect telegraph is subject to strange disturbances from terrestrial and atmospheric causes which admit sources of error beyond the control of the telegraphist. A flash of lightning in America may cause an extra dot in Europe, and *mine* may become *wine*. An earthquake in Japan may send a dash through France, and *life* would become *wife*. A wild goose flying against a telegraph wire might drive it into momentary contact with another wire, and *sight* might become *night*. Everyone should know his Morse alphabet, and people should learn how to write. Nine-tenths of the errors made are due to the execrable caligraphy of the present day. As a matter of fact, in ninety-nine cases out of a hundred, the telegraphist delivers to the editor of a newspaper 'copy' far more accurate than the first proof of his own leader submitted by the printer. The quantity of news transmitted is enormous, on an average 1,538,270 words are delivered per day. The recent convention in Chicago, when the Republican party of the United States nominated their candidate for the presidency, created so much business that every American paper has chronicled this big thing as unique. 500,000 words were sent on one night; but we in England, when Mr. Gladstone introduced his celebrated Home Rule Bill on April 8, 1886, sent from the Central Telegraph Office in London 1,500,000 words.

The growth of business has led to vast improvement in the carrying capacity of the wires. Cooke and Wheatstone required five wires for their first needle instrument to work at the rate of four words per minute. One wire can now convey six messages at ten times the speed. The first Morse apparatus could work at about five words a minute; we now transmit news at the rate of 600 words a minute. Even in 1875 it was thought wonderful to transmit messages to Ireland at 80 words a minute. When I was recently in Belfast I timed messages coming at the rate of 461 words a minute. Duplex working—that is, two messages travelling on the same wire at the same time in opposite directions, the invention of Gintl, of Vienna—is now the normal mode of working; Edison's quadruplex is common; and the Delany system of multiplex working is gradually being introduced, by which six messages are indiscriminately sent in either direction on one wire. The telegraphic system of England has been brought to the highest pitch of perfection. We have neither neglected the inventions of other countries, nor have we been chary of exercising

inventive skill ourselves, and we have received our full meed of that reward which is always freely bestowed on a British Government official, neglect and abuse.

All parts of the civilised world are now united by submarine cables. The 'Times' every morning has despatches from every quarter of the globe, giving the news of the previous day. 110,000 miles of cable have been laid by British ships, and nearly 40,000,000% of British capital have been expended by private enterprise in completing this grand undertaking. A fleet of 37 ships is maintained in various oceans to lay new cables and to repair breaks and faults—faults that arise, among other causes, from chafing on coral reefs, ships' anchors, the onslaught of insects, and earthquakes. The two cables connecting Australia and Java were recently simultaneously broken by an earthquake.

The politician, unmindful of the works of the engineer, is apt to apply to the credit of his own proceedings the growing prosperity of the world. The engineer, however, feels that steam and electricity in his hands have done more to economise labour, to cheapen life, to increase wealth, to promote international friendship, to alleviate suffering, to ward off war, to encourage peace, than all the legislation and all the verbosity of the politician.

The railways of this country are entirely dependent for the conduct of their traffic on the telegraph, and the security of their passengers is mainly due to the working of the block system. A railway, say between London and Bath, is broken up into certain short sections, and only one train is allowed on one section at one time. The presence, motion, and departure of trains are announced and controlled by electric signals, and the outdoor signals are governed by these electric signals. There are few more interesting places to visit than a well-equipped signal-box on one of our main railways. The signalman is able to survey the lines all around and about him by aid of his electric signals; he can talk by telegraph or by telephone to his neighbours and his station-master; he learns of the motion of the trains he is marshalling by the different sounds of electric bells; he controls his outdoor signals by the deflection of needles, or the movement of miniature semaphores; he learns the true working of his distant signals by their electrical repetition; machinery governs and locks every motion he makes, so that he cannot make a mistake. The safety of railway travelling is indicated by the fact that while in the five years ending 1878 thirty-five people were killed annually from causes beyond their own control, in the five years ending 1887 the average has been reduced to sixteen. One person is killed in 35,000,000 journeys made by train. Wherever we are dependent on human agency we are subject to human error, and a serious accident very recently at Hampton Wick has shown how the most perfect machinery may be rendered valueless to protect life when perversity, thoughtlessness, or criminality enter as factors into the case.

At the meeting of the Association in Plymouth in 1877, I was able for the first time in this country to show the telephone at work. Since then its use has advanced with giant strides. There are probably a million instruments at work now throughout the civilised world. Its development has been regularly chronicled at our meetings. As far as the receiving part of the apparatus is concerned, it remains precisely the same as that which I brought over from America in 1877; but the transmitter, since the discovery of the microphone by Hughes in 1878, has been entirely remodelled. Edison's carbon transmitter was a great step in advance; and the modern transmitters of Moseley, Berliner, D'Arsonval, De Jongh, leave little to be desired. The disturbances due to induction have been entirely eliminated, and the laws regulating the distance to which speech is possible are so well known that the specification of the circuit required to connect the Land's End with John o'Groat's by telephone is a simple question of calculation. A circuit has been erected between Paris and Marseilles, 600 miles apart, with two copper wires of 6½ gauge, weighing 540 lbs. per mile, and conversation is easily maintained between those important cities at the cost of three francs for three minutes. One scarcely knows which fact is the more astounding—the distance at which the human voice can be reproduced, or the ridiculously simple apparatus that performs the reproduction. But more marvellous than either is the extreme sensitiveness of the instrument itself, for the energy contained in one heat

unit (gramme-water-degree) would, according to Pellat, maintain a continuous sound for 10,000 years.

The influence which electric currents exert on neighbouring wires extends to enormous distances, and communication between trains, and ships in motion, between armies inside and outside besieged cities, between islands and the mainland, has become possible without the aid of wires at all, by the induction which is exerted through space itself. On the Lehigh Valley Railway, in the United States, such a system of telegraphing without wires is in actual daily use.

The conduct of telephonic business in England is still in the hands of those who hold the patents, and who maintain a most rigid monopoly. These patents have only a short period to run, and when they expire we may expect to find that England will not occupy the very retired position she holds now as a telephone country. Stockholm has more subscribers than London; there are 15,000 subscribers in and about New York; while the number in London is only 4,851.

Electric lighting has become popular, not alone from the beauty of the light itself, but from its great hygienic qualities in maintaining the purity and coolness of the air we breathe. The electric light need not be more brilliant than gas, but it must be more healthy. It need not be cooler than a wax candle, but it must be brighter, steadier, and more pleasant to the eye. In fact, it can be rendered the most perfect artificial illuminant at our disposal, for it can illumine a room without being seen directly by the eye; it can be made absolutely steady and uniform without irritating the retina; it does not poison the air by carbonic acid and carbonic oxide, or dirty the decorations by depositing unconsumed carbon; it does not destroy books or articles of vertu and art by forming water which absorbs sulphur acids; and it does not unduly heat the room.

In the Post Office Central Savings Bank in London it has been found, after two years' experience of electric lighting, that the average amount of absences from illness has been diminished by about two days a year for each person on the staff. This is equivalent to a gain to the service of the time of about eight clerks in that department alone. Taking the cost at the 'overtime' rate only, this would mean a saving in salaries of about 640*l.* a year. The cost of the installation of the electric light was 3,349*l.* and the annual cost of working 700*l.* per annum, say a total annual cost of 1,034*l.* The cost of the gas consumed for lighting purposes was about 700*l.* a year, so that on the whole there was a direct saving of something like 266*l.* a year to the Government, besides the material advantage of the better work of the staff resulting from the improved atmospheric conditions under which their work is done.

The production of light by any means implies the consumption of energy, and this can be measured in *watts*, or the rate at which this energy is consumed. A watt is $\frac{1}{746}$ part of a *horse-power*. It is a very convenient and sensible unit of power, and will in time replace the meaningless horse-power.

One candle light maintained by tallow	absorbs	.	.	124 watts.

" " cannel gas	"	.	.	48 "
" " electricity (glow)	"	.	.	3 "
" " electricity (arc)	"	.	.	5 "

The relative heat generation of these illuminants may be estimated from these figures.

Though the electric light was discovered by Davy in 1810, it was not until 1844 that it was introduced into our scientific laboratories by Foucault; it was not until 1878 that Jablochhoff and Brush showed how to light up our streets effectually and practically; it was not until 1881 that Edison and Swan showed how our homes could be illuminated softly and perfectly. Unpreparedness for such a revolution produced a perfect panic among gas proprietors; inexperience in the use of powerful electric currents resulted in frequent failure and danger; speculation in 1888.

financial bubbles transferred much gold from the pockets of the weak to the coffers of the unscrupulous; hasty legislation in 1882 restricted the operations of the cautious and the wise; and the prejudice arising from all these causes has, perhaps fortunately, delayed the general introduction of electricity; but now legislation has been improved, experience has been gained, confidence is being restored, and in this beautiful town of Bath fifty streets are about to be lighted, and we see everywhere around and about us in our English homes the pure glow lamp replacing filthy gas and stinking oil. The economical distribution of the electric current over large areas is annually receiving a fresh impetus. The expensive systems defined in the Act of Parliament of 1882 have entirely disappeared. Hopkinson in England and Edison in America showed how a third wire reduced the weight of copper needed by 66 per cent. Gaulard and Gibbs in 1882 showed how the conversion of alternate currents of high electromotive force to currents of low electromotive force by simple induction coils would enable a mere telegraph wire to convey sufficient electricity to light a distant neighbourhood economically and efficiently. Lane Fox in 1879 showed how the same thing could be done by secondary batteries; and Planté, Faure, Sellon, and Parker have done much to prove how batteries can be made to solve the problem of storage; while King and Edmunds have shown how the distribution by secondary batteries can be done as economically as by secondary generators. The Grosvenor Gallery Co. in London have proved the practicability of the secondary generator principle by nightly supplying 24,000 glow lamps scattered over a very wide area of London. The glow lamp of Edison, which in 1881 required 5 watts per candle, has been so far improved that it now consumes but $2\frac{1}{4}$ watts per candle. The dynamo, which in the same year weighed 50,000 lbs., absorbed 150 horse-power, and cost 4,000*l.* for 1,000 lamps, now weighs 14,000 lbs., absorbs 110 horse-power, and costs 500*l.* for the same production of external energy; in other words, its commercial output has been increased nearly six times, while its prime cost has been diminished eight times.

The steam-engine has received equal attention. The economy of the electric light when steam is used depends almost entirely on the consumption of coal. With slow-speed low-pressure engines one kilowatt (1,000 watts, $1\frac{1}{3}$ horse-power) may consume 12 lbs. of coal per hour; in high-speed high-pressure triple-expansion condensing engines it need not consume more than 1 lb. of coal per hour. Willans and Robinson have actually delivered from a dynamo one kilowatt by the consumption of 2 lbs. of coal per hour, or by the condensation of 20 lbs. of steam.

There is a great tendency to use small economical direct-acting engines in place of large expensive engines, which waste power in countershafting and belts. Between the energy developed in the furnace in the form of heat and that distributed in our rooms in the form of light there have been too many points of waste in the intermediate operations. These have now been eliminated or reduced. Electricity can now be produced by steam at 3*d.* per kilowatt per hour. The kilowatt-hour is the Board of Trade unit as defined by the Act of 1882, for which the consumer of electric energy has to pay. Its production by gas engines costs 6*d.* per kilowatt-hour, while by primary batteries it costs 3*s.* per kilowatt-hour. The Grosvenor Gallery Company supply currents at 7*d.* per kilowatt-hour; a 20 candle-power lamp consuming 3 watts per candle, and burning 1,200 hours per annum, expends 82,000 watt-hours or 82 kilowatt-hours, and it costs, at 7*d.* per unit, 50*s.* per annum. If the electricity be produced on the premises, as is the case in the Post Office, in the House of Commons, and in many large places, it would cost 20*s.* 6*d.* per annum. I have found from a general average under the same circumstances and for the same light in the General Post Office in London that an electric glow lamp costs 22*s.* and a gas lamp 18*s.* per annum. The actual cost of the production of one candle light per annum of 1,000 hours is as follows:—

										<i>s.</i>	<i>d.</i>
Sperm Candles	8	6
Gas (London)	1	3
Oil (petroleum)	0	8
Electricity, glow	0	9
„ arc	0	1 $\frac{1}{2}$

The greatest development of the electric light has taken place on board ship. Our Admiralty have been foremost in this work. All our warships are gradually receiving their equipment. Our ocean-going passenger ships are also now so illuminated, and perhaps it is here that the comfort, security, and true blessedness of the electric light are experienced.

Railway trains are also being rapidly fitted up. The express trains to Brighton have for a long time been so lighted, and now several northern railways, notably the Midland, are following suit. Our rocky coasts and prominent landfalls are also having their lighthouses fitted with brilliant arc lamps, the last being St. Katherine's Point on the Isle of Wight, where 60,000 candles throw their bright beams over the English Channel, causing many an anxious mariner to proceed on his way rejoicing.

Fontaine showed in Vienna, in 1873, that a dynamo was reversible; that is, if rotated by the energy of a moving machine, it would produce electric currents; or, if rotated by electric currents, it would move machinery. An electric current is one form of energy. If we have at one place the energy of falling water, we can, by means of a turbine and a dynamo, convert a certain portion of the energy of this falling water into an electric current. We transmit this current through proper conductors to any other place we like, and we can again, by means of a motor, convert the energy of the current into mechanical energy to do work by moving machinery, drawing tramcars, or in any other way. We can in this way transmit and utilise 50 per cent. of the energy of the falling water wherever we like. The waste forces of Nature are thus within our reach. The waterfalls of Wales may be utilised in London; the torrents of the Highlands may work the tramways of Edinburgh; the wasted horse-power of Niagara may light up New York. The falls of Bushmills actually do work the tramway from Portrush to the Giant's Causeway, and those of Bessbrook the line from Newry to Bessbrook.

The practicability of the transmission of energy by currents is assured, and the economy of doing this is a mere matter of calculation. It is a question of the relative cost of the transmission of fuel in bulk, or of the transmission of energy by wire. Coal can be delivered in London for 12s. per ton. The mere cost of the upkeep of a wire between Wales and London to deliver the same amount of energy would exceed this sum tenfold. For long distances the transmission of energy is at present out of the question. There can be no doubt, however, that for many purposes within limited areas the transmission of energy by electricity would be very economical and effective. Pumps are worked in the mines of the Forest of Dean, cranes are moved in the works of Easton and Anderson at Erith, lifts are raised in banks in London; water is pumped up from wells to cisterns in the house of Sir Francis Truscott, near East Grinstead; ventilation is effected and temperature lowered in collieries; goods, minerals, and fuel can be transmitted by telpherage.

The transmission of power by electricity is thus within the range of practice. It can be distributed during the day by the same mains which supply currents for light by night. Small industries, such as printing, watch-making, tailoring, boot-making, can be cheaply supplied with power. It is thus brought into direct competition with the distribution of power by steam as in America, or by air-pressure as in Paris, or by high-pressure water as in London; and the relative advantages and economies of each system are simple questions of calculation. When that evil day arrives that our supply of natural fuel ceases, then we may look to electricity to bring to our aid the waste energies of Nature—the heat of the sun, the tidal wave of the ocean, the flowing river, the roaring falls, and the raging storm.

There is a mode of transport which is likely to create a revolution in the method of working tramways. A tramcar carries a set of accumulators which supplies a current to work a motor geared to a pair of wheels of the car. The weight, price, day's work, and life of the accumulator is curiously the same as the weight, price, day's work, and life of horseflesh; but the cost of maintenance, the liability to accident, and the chances of failure are much less. Although very great improvements in batteries have been made, and they are now really practical things, sufficient experience in tramcar working has not yet been obtained to say

that we have reached the proper accumulator. Nor have we yet acquired the best motor and mode of gearing; but very active experiments are being carried out in various countries, and nothing can prevent their ultimate success.

The property, which the electric current possesses, of doing work upon the chemical constitution of bodies so as to break up certain liquid compounds into their constituent parts, and marshal these disunited molecules in regular order according to a definite law upon the surfaces of metals in contact with the liquid where the current enters and exists, has led to immense industries in electro-metallurgy and electro-plating. The extent of this industry may be gathered from the fact that there are 172 electro-platers in Sheffield and 99 in Birmingham. The term electro-metallurgy was originally applied to the electro-deposition of a thin layer of one metal on another; but this is now known as electro-plating.

In 1839 Jacobi in St. Petersburg and Spencer in Liverpool laid the foundations of all we know of these interesting arts. Copper was deposited by them so as to obtain exact reproductions of coins, medals, and engraved plates. The first patents in this country and in France were taken out by Messrs. Elkington of Birmingham, who still occupy the foremost position in the country.

The fine metals, gold and silver, are deposited in thin layers on coarser metals, such as german silver, in immense quantities. Christofle of Paris deposits annually six tons of silver upon articles of use and of art, and if the surfaces so electro-plated were spread out continuously they would cover 140 acres.

The whole of the copper plates used in Southampton for the production of our splendid Ordnance Survey maps are deposited by current on matrices taken from the original engraved plates, which are thus never injured or worn, are always ready for addition or correction, while the copies may be multiplied at pleasure and renewed at will.

Nickel-plating, by which the readily oxidisable metals like iron are coated with a thin layer of the more durable material nickel, is becoming a great industry; the trappings of harness, the exposed parts of machinery, the fittings of cycles and carriages, and innumerable articles of daily use are being rendered not only more durable but more beautiful.

The electro-deposition of iron, as devised by Jacobi and Klein, in the hands of Professor Roberts-Austen, F.R.S., is giving very interesting results. The designs for the coins which were struck at our Mint on the occasion of the Jubilee of the Queen were modelled in plaster, reproduced in intaglio by the electro-deposition of copper, and on these copper moulds hard excellent iron in layers of nearly $\frac{1}{10}$ th of an inch was deposited.

The exact processes of measurement, which have led to such vast improvement in our telegraphic systems, have scarcely yet penetrated into this field of electrical industry, and little is known at present of the exact relations of current and electromotive force with respect to surfaces of contact, rate of deposit, and resistance of liquids. Captain Sankey, R.E., of the Ordnance Survey Department, has done some useful work in this direction.

The extraction of metals from their ores by deposition has received wide application in the case of copper. In 1871 Elkington proposed to precipitate copper electrolytically from the fused sulphide of copper and iron known to the copper smelter as 'regulus.' Thin copper plates were arranged to receive the deposited copper, while the foreign metals, including gold and silver, fell to the bottom of the solution, the process being specially applicable, it was supposed, to regulus containing small quantities of the precious metals.

The electrical purification of copper from impure 'blister copper' or 'blade copper' has also made great progress, and special dynamos are now made which will, with an expenditure of 100 horse-power, precipitate 18 tons of copper per week. The impure metal is made to form the anode in a bath of sulphate of copper, the metal being deposited in the pure form on a thin copper cathode.

It was not very long ago considered very economical to absorb 85 horse-power in depositing one pound of copper per hour, but now the same work can be done with 3 horse-power. Mr. Parker of Wolverhampton has done good work in this direction, and his dynamos in Messrs. Bolton's works have revolutionised this process of purification.

Both at Swansea and Widnes immense quantities of copper, in spite of the restrictive operations of the copper syndicate, are being produced by electro-deposition. Copper steam pipes for boilers are now being built up of great firmness, fine texture, and considerable strength by Mr. Elmore at Cockermouth, by electro-deposition on a rotating mandril in a tank of sulphate of copper. By this process one ton of copper requires only a little more than one ton of coal to raise the requisite steam to complete the operation.

It has been shown that the electrolytic separation of silver from gold by similar methods is perfectly practicable. The value of the material to be dealt with may be gathered from the fact, communicated to the 'Gold and Silver Commission' now sitting, that nearly 90,000,000 ounces of silver are annually produced, and the greater portion of this amount contains sufficient gold to render refining remunerative. Although the old acid process of 'parting' gold and silver remains practically undisturbed, there seems no reason to doubt that in the future electricity will render us good service in this direction as it has already in the purification of copper.

There is not much actual progress to report in the extraction of gold from its ores by electrical agency. The conversion of gold into chloride of gold by the direct, or indirect, action of chlorine is employed on a very large scale in [Grass Valley] California and elsewhere. This fact has led to well-directed efforts to obtain, by electrolytic action, chlorine, which should attack finely divided gold suspended (with the crushed ore) in the solution from which the chlorine was generated, the gold, so converted into soluble chloride, then being deposited on a cathode. The process would seem to be hopeful, but is not as yet a serious rival to the ordinary chlorination method.

In the amalgamation of gold ores much is expected from the possibility of keeping clean, by the aid of hydrogen set free by the electric current, the surfaces of amalgamated plates.

It is well known that the late Sir W. Siemens considered that the electric arc might render good service in the fusion of metals with high melting-points, and he actually succeeded in melting 96 ounces of platinum in 10 minutes with his electrical furnace. The experiments were interrupted by his untimely death, but in the hands of Messrs. Cowles the electric arc produced by 5,000 ampères and 500 horse-power is being employed on a very large scale for the isolation of aluminium (from corundum), which is immediately alloyed (*in situ*) with copper or iron, in the presence of which it is separated.

The heating power of large currents has been used by Elihu Thomson in the United States, and by Bernardos in Russia, to weld metals, and it is said to weld steel without affecting its hardness. It has even been proposed to weld together in one continuous metallic mass the rails of our railways so as to dispense entirely with joints.

The production of chlorine for bleaching and of iodine for pharmaceutical purposes, the economical production of oxygen, are also processes now dependent on the electrolytic effect of the electric current.

It is almost impossible to enumerate the various general purposes to which electricity is applied to minister to our wants, and to add to our comforts. Every one appreciates the thorough efficiency of the trembling electric bell, while all will sooner or later derive comfort from the perennially self-winding electric clock. Correct mean time is distributed throughout the length and breadth of the land by currents derived from Greenwich Observatory. Warehouses and shops are fitted with automatic contact pieces, which, on any undue increase of temperature due to fire, create an alarm in the nearest fire station; and at the corner of most streets a post is found with a face of glass, which on being broken enables the passer-by or the watchful and active policeman to call a fire engine to the exact spot of danger. Our sewers are likely to find in its active chemical agency a power to neutralise offensive gases, and to purify poisonous and dangerous fluids. The germs of disease are attacked and destroyed in their very lairs. The physician and the surgeon trust to it to alleviate pain, to cure disease, to effect organic changes beyond the reach of drugs. The photographer finds in the brilliant rays of the arc lamp a

miniature sun which enables him to pursue his lucrative business at night, or during the dark and dismal hours of a black November fog of London.

We learn from the instructive and interesting advertising columns of our newspapers that 'electricity is life,' and we may perhaps read in the more historical portion of the same paper that by a recent decision of the New York Parliament, 'electricity is death.' It is proposed to replace hanging by the more painless and sudden application of a powerful electrical charge; but those who have assisted at this hasty legislation would have done well to have assured themselves of the practical efficacy of the proposed process. I have seen the difficulty of killing even a rabbit with the most powerful induction coil ever made, and I know those who escaped and recovered from the stroke of a lightning discharge.

The fact that the energy of a current of electricity, either when it flashes across an air space, or when it is forced through high resistance, assumes the form of heat of very high temperature led early to its employment for firing charges of gunpowder; and for many civil, military, and naval purposes it has become an invaluable and essential agent. Wrecks like that of the 'Royal George' at Spithead were blown up and destroyed; the faces of cliffs and quarries are thrown down; the galleries of mines and tunnels are excavated; obstructions to navigation like the famous Hell Gate, near New York, have been removed; time guns to distribute correct time are fired by currents from Greenwich at 1 P.M. In the operations of war, both for attack and defence, submarine mining has become the most important branch of the profession of a soldier and a sailor. Big guns, whether singly or in broadside, are fired, and torpedoes, when an enemy's ship unwittingly is placed over them, are exploded by currents of electricity.

An immense amount of research has been devoted to design the best form of fuse, and the best form of generator of electricity to use to explode them. Gun-tubes for firing consist of a short piece of very fine wire embedded in some easily fusible compound, while the best form of fuse is that known as the Abel fuse, which is composed of a small, compact mass of copper phosphide, copper sulphide, and potassium chlorate. The practice in the use of generators is very various. Some, like the Austrians, lean to the high tension effects of static electricity; others prefer magneto machines; others use the dynamo; while we in England cling with much fondness to the trustworthy battery. Since the electric light has also become such a valuable adjunct to war purposes, it is probable that secondary batteries will become of immense service. The strong inductive effects of atmospheric electricity are a source of great danger. Many accidental explosions of fuses have occurred. An experimental cable with a fuse at one end was laid below low-water mark along the banks of the Thames at Woolwich. The fuse was exploded during a heavy thunderstorm. The knowledge of the causes of a danger is a sure means for the production of its removal, or of its reduction to a minimum. Low tension fuses and metallic circuits reduce the evils of lightning, but have not removed them. Should war unhappily break out again in Europe, submarine mining will play a very serious part, and, paradoxical as it may appear—as has been suggested by the French ambassador, M. Waddington—its very destructiveness may ultimately prove it to be a powerful element of peace.

It seems incredible that, having utilised this great power of nature to such a wide and general extent, we should be still in a state of mental fog as to the answer to be given to the simple question—What is Electricity? The engineer and the physicist are completely at variance on this point. The engineer regards electricity, like heat, light, and sound, as a definite form of energy, something that he can generate and destroy, something that he can play with and utilise, something that he can measure and apply. The physicist—at least some physicists, for it is difficult to find any two physicists that completely agree with each other—regard electricity as a peculiar form of matter pervading all space as well as all substances together with the luminiferous ether which it permeates like a jelly or a sponge. Conductors, according to this theory, are holes or pipes in this jelly, and electrical generators are pumps that transfer this hypothetical matter from one place to another. Other physicists, following Edlund, regard the ether and electricity as identical, and some, the disciples of Helmholtz, consider it as an integral

constituent of nature, each molecule of matter having its own definite charge, which determines its attraction and its repulsion. All attempts to revive the Franklinian, or material theory of electricity, have, however, to be so loaded with assumptions, and so weighted with contradictions, that they completely fail to remove electricity from the region of the mysterious. It is already extremely difficult to conceive the existence of the ether itself as an infinitely thin, highly elastic medium, filling all space and employed only as the vehicle of those undulatory motions that give us light and radiant heat. The material theory of electricity requires us to add to this another incomprehensible medium embedded or entangled in this ether, which is not only a medium for motion, but which is itself moved. The practical man, with his eye and his mind trained by the stern realities of daily experience, on a scale vast compared with that of the little world of the laboratory, revolts from such wild hypotheses, such unnecessary and inconceivable conceptions, such a travesty of the beautiful simplicity of nature.

He has a clear conception of electricity as something which has a distinct objective existence, which he can manufacture and sell, and something which the unphilosophic and ordinary member of society can buy and use. The physicist asserts dogmatically: 'Electricity may possibly be a form of matter—it is not a form of energy.' The engineer says distinctly: 'Electricity is a form of energy—it is not a form of matter; it obeys the two great developments of the present generation—the mechanical theory of heat and the doctrine of the conservation of energy.' There must be some cause for this strange difference of views. It is clear that the physicist and the engineer do not apply the term electricity to the same thing. The engineer's electricity is a real form of energy; the speculative philosopher's electricity is a vague subjective unreality which is only a mere factor of energy and is not energy itself. This factor, like force, gravity, life, must, at any rate for the present, remain unknowable. It is not known what force is; neither do we know what is matter or gravity. The metaphysician is even doubtful as regards time and space. Our knowledge of these things commences with a definition. The human mind is so unimpressionable, or language is so poor, that writers often cannot agree even on a definition. The definition of energy is capacity for doing work. We practical men are quite content to start from this fiducial line, and to affirm that our electricity is a something which has a capacity for doing work; it is a peculiar form of energy. The physicist may speculate as much as he pleases on the other side of this line. He may take the factors of energy, and mentally play with them to his heart's content; but he must not rob the engineer of his term *electricity*. It is a pity that we cannot settle our difference by changing the term. Physicists might leave the term *electricity* to the form of energy, which is an objective reality, and which the ordinary mortal understands; while engineers would be quite content if speculative physicists and enthusiastic mathematicians would call their subjective unreality, their imaginary electrical matter, by some other term. If it be necessary to mentally create some imaginary matter to fulfil the assumptions and abstractions of their mathematical realisations, let them call it *coulombism* or *electron*, and not appropriate the engineer's generic and comprehensive term electricity. The engineer finds the motions of existing matter and of the ether quite sufficient to meet all his requirements, and to account for all those phenomena which are called electrical.

It seems paradoxical to assert that two unrealities can form a reality, or that two subjective ideas can become an objective one; but it must be remembered that in all electrical phenomena that which makes them real and objective is derived from without. The motion that renders an electrical phenomenon evident is imparted to it from some other form of energy. The doctrine of the conservation of energy asserts that energy is never destroyed, it is only transformed—work must be done to render it evident. No single electrical effect can be adduced which is not the result of work done, and is not the equivalent of energy absorbed. The engineer's notions of work—something done against resistance—and of power—the rate at which this change of condition is effected—are the keystones to the conception of the character of those great sources of power in nature whose direction to the uses and convenience of man is the immediate profession of those who

generally assemble together in Section G of the British Association to discuss the 'practical application of the most important principles of natural philosophy which has, in a considerable degree, realised the anticipations of Bacon and changed the aspect and state of affairs in the whole world.'

I cannot pretend to have given a survey of all the practical applications of electricity. I have entirely neglected its applications to physical research, its assistance in securing minute and accurate observations, the marvellous precision and delicacy of its measurement. I have but briefly indicated the present area covered by the new and rapidly growing industry. Five million people upon the globe are now dependent on the electric current for their daily bread. Scarcely a week passes without some fresh practical application of its principles, and we seem to be only on the shore of that sea of economy and beneficence which expands with every new discovery of the properties of electricity, and spreads already beyond the mental grasp of any one single worker.

The following Papers were read:—

1. *The Phonograph.* By Colonel G. E. GOURAUD.

2. *The Graphophone.*¹ By HENRY EDMUNDS.

A review of the interesting history of the art of recording and reproducing sound shows that Dr. Hooke in 1681 exhibited some experiments before the Royal Society demonstrating how musical notes and other sounds could be produced by means of toothed wheels rapidly rotated. In 1854 Charles Bourseuil proposed to use two diaphragms, connected by an electric wire, and, by speaking into one of them, reproduce the spoken sounds at any distance in the other. This idea was actually carried out by Philipp Reis five years later. The Phonautograph was patented by Leon Scott in 1857; and Faber constructed a complicated speaking machine which pronounced a few words and sentences most unsatisfactorily. But in 1876 appeared the Bell Telephone, the first really perfect instrument for the transmission of speech. In April, 1877, M. Charles Cros deposited a paper at the Academy of Sciences in Paris on 'A process of recording and reproducing audible phenomena,' in which he proposed to obtain tracings of sound-waves by means of a vibrating membrane. Then, by going over these tracings with a stylus attached to another membrane, the sounds would be reproduced. Consequently, to M. Cros belongs the credit of having suggested a means of mechanically recording and reproducing spoken sounds. Later in the year Mr. Thomas Alva Edison realised this idea in his phonograph. Mr. Edmunds described it in a report to the 'Times' on February 17, 1878. Shortly afterwards Mr. W. H. Preece exhibited at the Royal Institution the first phonograph made in this country under Mr. Edmunds' instructions. This instrument created a great sensation, and glowing anticipations were entertained of its future application, but it was found that its articulation was far too imperfect, and its general performance too crude, to admit of its being used for any practical purpose; and Mr. Edison himself gave it up, applying himself to other work, even allowing his two English patents to lapse. But in 1881, Professor Graham Bell, inventor of the Telephone, with Dr. Chichester A. Bell, and Mr. Charles Sumner Tainter, formed the Volta Laboratory Association in Washington for the purpose of investigating the art of transmitting, recording, and reproducing sound. They conducted many elaborate experiments, and, among other things, sought for and discovered the cause of the failure of the Edison Phonograph. They found that tinfoil, as used in that instrument, was far too pliable for the purpose, as it always had a tendency to pucker, and destroy the symmetry of the sound-waves. They perceived that no good result could be obtained by merely *indenting a pliable material*; it was necessary to *engrave a record in a solid resisting body*; and this discovery enabled them to produce a really practical instrument, which they termed the 'Graphophone.' Instead of tinfoil, Mr. Tainter employed

¹ Printed in extenso in *Engineering*, vol. xlv. p. 319.

wax, ploughing out, by means of a vibratory stylus, a narrow undulating groove, which constituted a sound record. When this groove was retraced by another stylus and diaphragm, the original sounds were reproduced with a fidelity undreamed of by those only acquainted with the phonograph. In 1885 the Volta Laboratory Association was dissolved, after performing most important work, and taking out a series of valuable patents.

Mr. Tainter has brought the experience of years to the perfection of the graphophone. The kernel of the invention is the 'recording cylinder,' six inches long by an inch-and-a-quarter broad, formed of cardboard, coated with wax. This is placed in a small lathe and rotated by a treadle in contact with the 'recorder,' which consists of a metal frame supporting a thin mica diaphragm, in the centre of which is a steel point that cuts a narrow groove on the surface of the cylinder, according to the quality and intensity of the sound spoken against it. The recorder is then removed, and replaced by the 'reproducer,' a light feather of steel that travels along the grooves made on the cylinder, and transmits their undulations to a small mica diaphragm, which in its turn communicates its vibrations, as sound-waves, to the ears of the auditor by means of two india-rubber tubes, for Mr. Tainter found it best to reduce the size of the record, and concentrate the sound in this way, on account of the greater distinctness that was thus secured. The manipulation of the graphophone is simplicity itself. It requires no adjustment, no electric motor, no galvanic battery. The foot supplies the motive power, and the machine regulates its own speed by means of an ingenious, but simple governor. Journalists and reporters may dictate their articles and reports, leaving others to transcribe them. The principal of a firm can speak his day's correspondence into the machine, which will repeat it sentence by sentence, to be written down in proper form by pen or typewriter. Or purely verbal communication can be carried on through the post by means of the record cylinders, which are extremely light, although capacious enough to hold one thousand words a piece. All these applications are now in active operation in America, where the graphophone has achieved a great success.

3. *Mechanical Pathology considered in its relation to Bridge Design.*¹

By G. H. THOMSON, *M.Am.S.E.*

After pointing out the applicability of the ordinary terms of medical science in the consideration of mechanical problems the author asks, How many railway bridges are structurally competent to perform the work for which they were erected? How many are being taxed mechanically beyond the limit ever intended? And how many are able to withstand the sometimes rough usage (as in the case of collisions) incidental to railroad operations?

A railway bridge is ordinarily constructed upon the assumption that all the conditions governing its use and life will always remain favourable, and the non-recognition of the fact that an unfavourable combination of circumstances may occur is responsible for many of the deficiencies that occur in practice.

No less than 251 truss railway bridges have failed in the United States and Canada during the ten years ending December 1887 from preventable causes such as are here alluded to, involving in each case the wreck wholly or partially of a train.

The author investigates the causes of these several accidents under different headings. He discusses successively broken axles and wheels, increase of tonnage, power, and speed.

He doubts the utility of laboratory tests as a means of affording thoroughly reliable information in regard to broken axles, and points out that whereas the earliest engine used in America only weighed 0.875 ton per wheel, those now in use weigh eight tons and upwards. Since 1874 the speed of freight trains on the New York Central has increased from fifteen to twenty-five miles per hour, and passenger trains at times attain a maximum speed of no less than 74 miles an hour.

¹ Printed in *extenso* in *Engineering*, vol. xlvi. p. 252.

The author then discusses certain experiments he has made with a view to ascertain the strains that occur in various types of bridge when loads pass over them, and proceeds to describe an extensive series of photographs illustrative of bridge accidents, which were exhibited to the meeting.

In concluding he strongly advocates the use of riveted lattice-bridges instead of pin-connected trusses for railway service up to spans of 250 feet, and gives numerous reasons for preferring them, as well as conditions to be observed in their construction.

4. *A few Arguments in favour of Light or Road Railways.*

By THOS. STEPHEN P. W. D'ALTE SELLON, *Assoc.M.Inst.C.E.*

The author's object in this paper has been to demonstrate that there is no reason why the present tramway system, familiar in most of our principal towns, cannot be made (with some modifications) of exceptional value as feeders to the trunk lines, and as a means of transit for every description of goods and merchandise as well as passengers.

That, by utilising the sometimes considerable waste, so often met with along the side of our country roads, cheap and efficient feeders can be constructed, thereby saving the cost of land purchase or the heavy cost of maintenance if constructed on the road.

For example, a line which has been constructed on this principle and has been working for the last eighteen months, is mentioned as proving how increased facilities make increased traffic, in the fact that it carries the entire population of the whole district once a week besides dealing with the whole of the cartage and delivery of goods to and from the London and North-Western Railway, with which the line is connected, as well as all the parcels and mails.

That, besides the advantages proved by the large patronage it receives, the property in the district, since its opening, has risen 20 per cent. in value, and houses which had long been in want of tenants are now all occupied.

That, as the object of this class of railway is to carry heavy goods and other merchandise that would otherwise be drawn along the road, it is clear that there must be a great saving in the wear and tear of the same as well as a material relief to the road rates which, in some country districts, is a great burthen.

Being a tramway, the working expenses as compared with railways are very small, owing to the absence of stations and station officials, signals and telegraph.

The author is strongly against the construction of this class of light railway to any other gauge but that of the line it feeds, as he affirms that the plea of economy cannot be maintained, and that one of the chief causes of the failure of the Irish Tramway Act, 1883, was the fact that the gauge was fixed at 3 ft., the fallacy of which has been demonstrated by the report of the late Royal Commission on Irish Public Works.

He also points out the great necessity there is for the reform of Private Bill Legislation, there being far too much expense in the introduction of a scheme, *i.e.*, prior to consideration; a mutilated Bill being often accepted by the promoters in consideration of the money already expended.

In these days of progress landowners are urged to thoroughly examine the merits of a scheme before they throw away their money in opposition, as by arrangement with promoters all their objections might easily be overcome.

By a comparison between the ordinary service of a branch line and the ordinary service of a light railway, it is demonstrated by the actual returns of the latter that it is to the interest of all railway managers and railway shareholders to give every facility for the construction of these feeders which must largely increase the value of their properties.

FRIDAY, SEPTEMBER 7.

The following Papers were read:—

1. *The Barry Docks.*¹ By JOHN WOLFE BARRY, *M.Inst.C.E.*

The Barry Docks, which are now approaching completion, are situated on the north shore of the Bristol Channel about 7 miles westward of Cardiff. The site is between Barry Island and the mainland, and the approaches from the sea are very easy. Good anchorage exists eastward of the docks between Barry Island and Sully Island. The docks are, as is the case with other docks on the Bristol Channel, tidal, and thus can only be approached for a few hours at high water. The range of tide in the Bristol Channel is large: at Barry there is a range of 36 feet at ordinary springs and of 19½ feet at ordinary neaps. There is a depth of 25 feet of water at low water of spring tides within 700 yards of the entrance gates of the Barry Docks. The main object of the Barry Docks is for the shipment of South Wales coal, but it is expected that a considerable import trade will also be developed. About 11 millions of tons of coals were shipped at the neighbouring ports of Cardiff and Penarth during the past year. The Barry Docks are connected with the coal-fields by new railways about 27 miles in length which are nearly finished. They have easy gradients, which, on the main line, are not steeper than 1 in 400 against the load. The entrance of the docks is on the east side of Barry Island, which protects it from westerly and south-westerly winds. Against other winds the entrance is protected by two breakwaters composed of rubble protected by 6-ton blocks of stone on the sea-slope. The waterway between the breakwaters is 350 feet and the entrance is 485 yards within the breakwater heads. A channel of that length is to be dredged to the entrance. The entrance is 80 feet wide and has a pair of wrought-iron gates which will be opened and closed by direct acting hydraulic cylinders; it gives access to the basin, which is 600 feet long and 500 feet wide, having an area of 7 acres. Beyond the basin is the dock, which is 3,400 feet long and 1,100 feet wide. This width is divided at the western end of the dock into two arms by a projecting mole. The water area of the dock is about 70 acres. The basin and dock are connected by a passage, which, like the entrance, is 80 feet wide, and has a pair of wrought-iron gates. The basin will be used as a lock, and the water in it will be adjusted to meet the rising tide each day, so that vessels may leave the basin before high water, and, similarly, vessels may enter the basin for some little time after high water. A floating caisson of wrought iron has been provided, which will fit against any of the faces of the entrance or passage in case of necessity. A low-water lock westward of the basin is contemplated. A graving dock, 700 feet long and 100 feet wide, is being made at the north-east corner of the dock. Eastward of this is the timber pond of 24 acres, approached from the dock by a short canal. The total area of water in the dock, basin, and timber pond is upwards of 100 acres. The depth of water at the entrance is 38 feet at high-water spring tides, and 29 feet at high-water neap tides. The following list gives the levels of various parts of the dock and of the tides above a datum line 50 feet beneath Ordnance datum:—

	Above Datum Feet
Ordnance datum	50·00
High water—ordinary <i>spring</i> tides	69·70
Low water	33·60
High water—ordinary <i>neap</i> tides	61·30
Low water	41·70
Mean sea-level at Barry	51·60
Entrance channel	28·00
Sill of entrance	32·00 ²
Sill of passage	32·00 ²

¹ Printed *in extenso* in the *Railway News*, Sept. 15, 1888.

² The sills being in the form of an invert, at the middle point there is three feet more water than the nominal level above given.

	Above Datum Feet
Bottom of basin	30.00
Bottom of dock	30.00
Coping of basin and dock	76.50
Top of breakwaters	78.50

The shipment of coal will take place from eleven high-level coal-tips and four cranes on the north side of the dock, and five low-level tips on the mole, and one tip at the west end of the dock. Space for a larger number of tips exists on the mole and on the south side of the dock and in the basin. Imports will be accommodated on the south and east sides of the dock. All the machinery will be worked by hydraulic pressure from an engine-house and accumulators at the south side of the dock, and two other accumulators on the north side of the dock. The first sod of the dock was cut in November 1884, and it is expected that the docks will be opened at the end of this year or the beginning of 1889. The engineers for the dock works are the author and Mr. T. Forster Brown and Mr. H. M. Brunel; the resident engineer is Mr. John Robinson. The contractor for the dock works is Mr. T. A. Walker. The cost of the dock works will be about 850,000*l.*, including the gates and all the hydraulic and other machinery, electric light, &c.

2. *Plant and Machinery in use on the Manchester Ship Canal.*¹ By LIONEL B. WELLS, *M.Inst.C.E.*

When the Association met at Manchester last year Mr. Leader Williams read a paper giving a general description of the Manchester Ship Canal, and the author proposes to give some account of the means adopted by Mr. T. A. Walker, the contractor, for carrying out the work.

The Canal commences at Eastham, 5 miles above Liverpool, and extends to Manchester, 35½ miles further inland, and is practically a continuous cutting. The Canal is to be more than half as wide again as that of Suez, and, with extensive docks and the deviations of the various railway lines to provide for, the earthwork amounts to about 50 million cubic yards.

The engineer has divided the work into sections, and appointed a resident engineer to each. The contractor divides the work into nine sections; each section is assigned to an agent, with a separate staff of sub-agents and engineers looking to the agent for instructions. To their charge is consigned the plant allotted to each section; they have their own workshops, means of repairing plant, &c. The whole is controlled by an agent-in-chief with head-quarter staff in Manchester; but each section is worked as a separate contract; the individual responsibility of the agent is thus secured by Mr. Walker, and the Canal Company hold Mr. Walker responsible for his contract to complete the whole of the work.

A commencement was made during the winter, and already the progress has been very great, mainly with excavation, and especially on the sections at Eastham and Manchester.

The plant for a contract of such magnitude, to be completed within a limited time, is necessarily great in quantity and of the most improved description. In addition to the usual locomotives, which already number eighty-seven, there are upwards of sixty steam-diggers of various models, some of which were referred to in detail and photographs shown; also new excavating machines were described, which, under the name of the French or German Excavator, for each nation supplies its especial machine, have been for the first time introduced into this country. The action of the machine is that of a bucket-dredger, but instead of being water-borne it is worked on a railway.

Already the excavations exceed a million and a quarter cubic yards a month, and the output is still increasing.

¹ Printed in *extenso* in the *Engineer*, Sept. 21, 1888.

3. *On an improved Canal Lift.*¹ By S. LLOYD.

After referring to the antiquity of river and canal navigation, the author mentions that no effective method of overcoming the difficulty of transferring boats from one level to another was invented till the year 1481, when, by the introduction of canal locks with double gates, a new era in canal construction was introduced, as canal boats, instead of being confined to transit across level plains, could be made to traverse hills and valleys wherever a sufficient supply of water could be obtained.

The author points out that as a rule canals have not a sufficient supply of water to work locks of a capacity to suit the larger class of boats which modern trade renders necessary for economy of transit; but a new era in canal transit may be again inaugurated by the use of hydraulic lifts of the improved type, which experience shows would be desirable, and which it is the object of his paper to describe.

Already three hydraulic canal lifts are in operation, namely, one at Anderton in Cheshire, one at La Louvière in Belgium, and another at St. Omer in France.

In each case the boat is floated into a receptacle full of water, and is raised or lowered in it, the receptacle being supported by a ram fixed vertically beneath it.

With a view to augment the stability of such lifts, it has been proposed to increase the number of points of support of the receptacle by placing more rams and presses under it; but this would not attain the desired result, and would be very expensive, requiring many deep, and therefore costly, foundations.

The improved hydraulic canal lift, of which diagrams are shown, suspends the receptacle between and considerably below the upper part of two hydraulic rams in place of making it rest on the head of one ram.

This new arrangement causes the centre of gravity of the system to be very low down, even below the stuffing-boxes of the hydraulic presses (if desired), and consequently great stability is attained. It not only insures very great stability, but at the same time effects considerable economy in construction.

The heads of the two rams are connected by a cross-girder, to which the receptacle is suspended by ties; and the strong pipes below, which connect the two presses, ensure solidity and perfectly even movement of the receptacle.

By this arrangement the rams have not to descend entirely below ground, so that the wells for the presses are not nearly so deep, and consequently are less costly. Moreover, the rams can be easily lubricated with oil, and all the parts are readily accessible for inspection or replacement.

The advantages of rapidity and economy with which boats of large tonnage may be transferred from one level to another by the means advocated will be apparent.

4. *On the Replenishment of the Underground Waters of the Permeable Formations of England.* By J. BAILEY DENTON, *M.Inst.C.E., F.G.S.*

The author, having long advocated, with the late Sir John Rennie and others, the storage of the surplus rainfall in reservoirs or lakes to be constructed in the higher tributary valleys of our river systems to maintain them in full service, invites attention to the capabilities existing of replenishing at the same time the subterranean supplies of the water-bearing strata by shafts to be sunk down to the line of their saturation.

The author takes the Thames and its basin to illustrate his views, which apply equally to other river systems, and to support his statement as to the decline of the water levels in the chalk, red sandstones, and other formations, he makes reference to the evidence and publications of Clutterbuck, Deacon, Harrison, Braithwaite and others, who have shown that with a natural inclination towards the outfall the line of saturation in the chalk under London, and in the sandstone at Liverpool, had fallen, more than twenty years back, above fifty feet. The most reliable

¹ Published *in extenso* by the author. (J. Hogg and Sons, London.)

records of meteorologists showing that the average amount of rain falling on the surface of the Thames watershed varies according to position from 25 inches to 28½ inches, he has assumed that 27 inches is the nearest approach to the mean quantity upon which the supply of the Thames system depends. Out of the three and a half million acres constituting approximately the superficial area of the Thames watershed he estimates that one-third represents the aggregate of impervious surfaces consisting of clays, gault, and lias, whilst two-thirds represent in like way the numerous formations and beds of chalk, sandstones and sand-beds, cornbrash and coral rag, and marlstones, the former throwing off the rain, and the latter absorbing and infiltrating nearly all that falls upon it to satisfy vegetation and evaporation and to find discharge by springs at the outcrops.

Of the 27 inches forming the mean average annual rainfall, about two-thirds, or eighteen inches, are evaporated from the surface, whilst of the remaining third 4 inches serve to maintain the river system, and 5 inches pass away as floods and freshets. Instances are numerous in which the year's rainfall exceeds 30 inches, whilst they are very few in which it is less than 20 inches—about three times in twenty years. As the amount of evaporation is nearly a constant figure, and the quantity required to maintain effectually the river system necessarily remains the same under all conditions, the amount of flood or excess water greatly varies. It is sometimes double the average. On the few occasions when the rainfall does not reach 20 inches it is insufficient to satisfy the demands of the river system, and then the river becomes a borrower from the stored supply of the subterranean reservoirs. On such occasions the quantity of water flowing down the river to Kingston has been so reduced as not to reach 300 million gallons in twenty-four hours. The importance and bearing of this fact upon the proposal to replenish the subterranean supply will be appreciated when it is pointed out that the quantity of water supplied daily to the metropolis by the water companies has already exceeded 150 million gallons. Of these 150 millions the river Thames contributes 50 per cent. or 75 millions, which is a quarter of the quantity flowing past Kingston. The Lea furnishes 38 per cent., and deep chalk wells the remainder, or 12 per cent. The quality of deep well waters has become of late years more and more approved. Dr. Edward Frankland, in his classification of potable waters, places deep well waters only second to springs issuing from the outcrops of the same formations. To make good the loss of this superior water the author proposes that whenever the water in the river rises above a certain datum height recognised as the gauge of its full service, the excess shall be diverted out of the river course on to filter-beds formed near at hand. The outlet from these filter-beds would be steined shafts or sumps sunk down to the water-level beneath, and into them the filtered water would pass after it is freed from flocculent matter. The steined shafts would be made water-tight and sealed against all surface contamination. The whole of the 150 million gallons forming the metropolitan supply of the water companies is, with exception of the Kent Company's supply, at present filtered daily through filter-beds varying in depth and character of materials from 3 feet 6 inches to 9 feet deep of sand and other ingredients of different degrees of coarseness, the whole of the beds covering a superficial space rather less than 100 acres in extent. These arrangements having been successfully worked, the same might be adopted in the utilisation and purification of excess or storm waters.

As far back as 1867 the author in his evidence before the 'Royal Commission on Water Supply' pointed out that if towns on the banks of rivers, such as the Thames, the Lea, and their tributaries, were to lift their sewage and foul liquids on to absorbent lands lying 100 to 150 feet above them, they would not only free those rivers from pollution but they would help to maintain their flow with certainty. He specified Luton as a town that could adopt such a mode of disposal with good effect and economy (see Question 1613 of Minutes of Evidence). The author now refers to this case in consequence of the authorities of Luton having adopted the treatment by which they have signally proved the facility with which the sewage of towns may be cleansed by filtration through a deep bed or stratum of porous material. Winchester, Basingstoke, and several other towns situated on the chalk have adopted this mode of sewage disposal without any injurious effect.

The author submits that while such instances testify to the purifying powers of aërated chalk, they afford proof that when superfluous waters are let down into the water-bearing strata from above, they will *pro tanto* spread and naturally raise the line of saturation and the outflow of springs.

5. *The Raiyān Project for the Storage of Nile Flood.*¹

By COPE WHITEHOUSE, M.A.

This paper described a project for impounding a part of the surplus flood of the Nile. A series of surveys show that the Wadi Raiyān is a depression 75 miles to the S.S.W. of Cairo, communicating with the Nile Valley at +26 metres, or a little below high Nile. Except at two narrow passes, it is bounded by precipitous limestone hills rising to +190 metres. The bottom, of sand and clay overlaying rock, sinks to -46 metres. A reservoir formed by putting this valley in communication with the Nile flood would have at +20 metres a surface of 686 sq. kil. (250 square miles), or 686 million square metres, and hold 20,559 million cubic metres. At +20 metres the surface is 550 million square metres, and contents 14,876 million cubic metres. It would yield (without pumping) a net 40 million cubic metres per diem for 100 days, or about the average discharge of low Nile from March to July. It would practically double the summer (Sefi) irrigation of Egypt.

The proposed works are:—

- (a) Cutting through the Myana Col:—3,500 metres long; summit level, +44; bed of canal, +21.8; average, 14 metres; material (hard clay) to be removed, about 75,000 cubic metres for each metre of bed width.
- (b) Dyke skirting desert: depth of water held up, 8 metres; section, 140 square miles; length, 14,500 metres; material (gravel, sand, and earth) to be handled, about 2 million cubic metres.
- (c) Short low cut (1,500 metres); two short banks (500 metres); and a regulator.

The works could be completed within one year, and the Wadi Lulu and Wadi Safir, being detached from the Wadi Raiyān, could be used as small reservoirs until the Raiyān Basin was available. It would require one season to fill the small basins, and three to fill the Raiyān Reservoir.

6. *The Severn Watershed.*² By J. W. WILLIS BUND.

The Severn Watershed, with an area of 4,350 square miles, is the second largest in England and Wales. The water supply within its area is no more than sufficient for the population (1,500,000) and trades of the district.

1. THE PRESENT SOURCE OF SUPPLY.

The Severn, from its source to Beachley, in Gloucestershire, is 158 miles long, and its drainage area of 4,350 square miles, comprises parts of the following ten counties:—Montgomery, Denbigh, Radnor, Salop, Stafford, Northampton, Warwick, Worcester, Hereford, and Gloucester.

The Severn rises in one of the Montgomeryshire spurs of Plynlimon, about 2,000 feet above sea-level. At Llanidloes, 15 miles down, it is only 545 feet above sea-level; at Newtown, 12 miles, 358 feet; at Montgomery, 8 miles, 306 feet; at Welchpool, 8 miles, 270 feet; at Shrewsbury, 32 miles, 179 feet. The fall of the river in the 75 miles of its upper course is 1,821 feet; at the end of the next 30 miles (Bewdley) the fall is 108 feet (179 to 71); at Stourport it is 53 feet; at Worcester, 35 feet. In the next 40 miles, to Framilode, the fall is about

¹ See *Engineering*, vol. xlvi. p. 267.

² Paper published *in extenso* in the *Report of Severn Fishery Board* for 1888.

3 inches a mile, or 9 feet 8 inches. After Framilode, round the Horseshoe bend, it is about 1 foot per mile.

From Llanidloes to Sharpness, 140 miles, at mean sea-level the fall is 545 feet. The tide flows up regularly to Tewkesbury, and a 28-feet tide at Sharpness puts the Navigation Weir at Tewkesbury out of action. This occurs on an average four times a month. The tide runs up to Upton, and on very high tides is still felt at Worcester.

(i) THE SEVERN TO TEWKESBURY.

Area, 640 square miles ; rainfall, 20·26. Except about 20 square miles of the Upper Leaddon, which is partly porous, all the rocks of the Lower Severn are superpervious.

(ii) THE AVON.

Falls into the Severn at Tewkesbury ; 26 feet above sea-level ; 85 miles long, falls 226 feet (252 to 26) ; drains 1,040 square miles ; rainfall, 20·11 inches. Except a patch of pervious rock in the N.E. corner, all of the basin is composed of superpervious rocks.

(iii) MID SEVERN.

Tewkesbury to Shrewsbury, leaving out the Teme ; fall, 153 feet (from 179 to 26) ; drainage area, 1,050 square miles ; rainfall, 19·54 inches.

(iv) TEME.

Falls into Severn about 2 miles below Worcester ; about 27 feet above sea-level ; length, 64 miles ; fall, over 500 feet ; drainage area, 633 square miles ; rainfall, 22·91 inches. The rocks are impervious, 250 square miles ; partly pervious, 300 square miles ; superpervious, 50 square miles.

(v) UPPER SEVERN.

Shrewsbury to the source, leaving out the Vyrnwy ; fall, 1,821 feet (2,000 to 179) ; length, 75 miles ; drainage area, 631 square miles ; rainfall, 22·91 inches ; impervious rock, 250 square miles ; partly porous, 381 square miles.

(vi) VYRNWY.

Falls into Severn at Molverley ; 217 feet above sea-level ; length, 29 miles ; fall, 1,283 feet (1,500 to 217) ; drainage area, 339 square miles ; rainfall, 29·67 inches ; impervious rocks, 330 square miles ; porous, 5 square miles.

The proportion of rock impervious, partly pervious, superpervious, and pervious throughout the 4,350 square miles of the watershed is as follows :—

	Square miles
Impervious	840
Partly pervious	825
Superpervious	2,100
Pervious	585

The area of high rainfall is almost coextensive with the area of impervious rock.

2. RAINFALL.

Taking the mean annual rainfall by counties, the figures are for 1887 :—

	Inches
Montgomeryshire	31·67
Shropshire	23·90
Worcester	19·85
Gloucester	22·18
Hereford	19·53
Stafford	21·19
Warwick	18·42

or for the watershed 22·38 inches.

As to monthly rainfall, September is the wettest month on a 20 years' average at 7 places, 3·38 being the figure. The driest is March, 1·86. As to distribution of rainfall, the N.W. corner of the watershed is wettest, and the rainfall gradually decreases as far as the N.E. corner, 25 to 30 inches. This remains the average, going south, until the Avon watershed is reached, when it does not exceed 20 to 30 inches ; and among the Cotswolds it rises to from 25 to 35 inches.

On the west there is a triangular area of high rainfall, of which the Severn, from Llanidloes to Shrewsbury, is the base, and the apex is at Coleford, in the Forest of Dean, and the two sides are the watershed line and the Severn. Over this area the rainfall is from 30 to 40 inches.

Height above sea-level does not seem to be a safe guide to the rainfall in the district, as the following figures from four of the counties will show :—

	Height in feet	Rainfall Average of 3 years
<i>Montgomeryshire—</i>		inches
Tybrith	595	46·12
Montgomery	550	29·51 ¹
Churchstoke	540	31·52
<i>Shropshire—</i>		
Bishopscastle	720	32·72
Church Stretton	702	30·06
Westbury	700	33·17
<i>Worcestershire—</i>		
Lincombe	62	27·38
Bevere	52	29·07
Diglis	49	26·60
<i>Gloucestershire—</i>		
Westbury-on-Severn	62	31·20
Frampton	42	27·72
Llanthony	39	26·25

3. THE PRESENT SUPPLY AND DEMAND.

Taking the rainfall over the district at 25 inches, roughly, the present demand on the water supply is, primarily, that due to the following population :—

	Population
Montgomeryshire	60,000
Denbighshire	5,000
Radnorshire	5,000
Shropshire	280,000
Stafford	280,000
Warwick	100,000
Worcester	390,000
Hereford	20,000
Gloucester	360,000
Total	1,500,000

Taking the supply at 20 gallons a head per day, including manufacturing purposes, it gives 30,000,000 gallons ; Liverpool and what is taken for the Shropshire Union Canal takes 50,000,000 gallons a day ; mills, navigation, and to keep up the head of water, 20,000,000 gallons (a very low estimate). So that at the lowest the present demand is 36,500,000,000 gallons a year.

¹ One year only (1885).

The supply is 25 inches on 4,350 square miles. An inch of rain is 14,500,000 gallons to the square mile. The amount is 1,576,875,000,000 gallons.

Deduct from this evaporation and absorption 20 per cent., 5 inches of rainfall waste by floods 20 per cent., 5 inches rainfall. This amounts to 10 inches, 630,750,000,000 gallons. Add to this 36,500,000,000 gallons (the present daily demand), and the total is 667,250,000,000 gallons. Deduct this from the present supply of 1,576,875,000,000 gallons, and the surplus over the present demand is about 909,625,000,000 gallons.

4. THE RELATION BETWEEN THE RAINFALL AND THE HEIGHT OF THE RIVER.

1. What rainfall in what parts of the watershed is required to produce a flood? Broadly, the rainfall on the east bank in Staffordshire and Worcestershire never causes floods, for—

- (1) The tributaries are too small to bring down the necessary volume of water.
- (2) The porous nature of the rocks.
- (3) The low rainfall.

To produce a flood the Montgomeryshire rainfall is required in addition.

2. Local storms, however violent, produce but small effect on the river.

(a) August 4, 1886, rainfall at Lincombe, 2·43 inches. The height of the river at Diglis and Tewkesbury on the next days was:—

	DIGLIS		TEWKESBURY	
	feet	inches	feet	inches
August 5	10	3	11	0
„ 6	10	6	11	3
„ 7	12	8	11	0

Besides the Lincombe rainfall on August 4 there had been in Montgomeryshire falls of 1·41 inch at Dolanog, and 1·88 inch at Pennant, and on the 5th 2·00 inches at Llansaintffraid. The water took two days to reach Diglis. The local fall at most raised the river there 3 inches.

On September 19, 1886, there was a fall of 1·68 inch on the Banw, but the Severn at Diglis remained unaffected for the next week at 10 feet 5 inches. Indeed the height gradually fell. To raise the Severn at Diglis there must be at least 20 inch of rain over most of Montgomeryshire.

The following figures show the Montgomeryshire rainfall and the height of the Severn at Diglis for 1887, and also the mean rainfall for the counties of Salop and Stafford:—

	Mean Rainfall in Montgomeryshire	Mean Rainfall in Stafford and Salop	Height of Severn at Diglis	
	inches	inches	ft.	ins.
January	2·71	2·69	17	5
February	1·08	·69	13	2
March	1·66	1·54	11	7
April	1·54	1·25	10	10
May	2·08	1·92	10	9
June	1·08	1·63	11	0
July	1·83	1·48	9	7
August	3·89	2·63	9	6
September	3·08	2·32	10	9
October	2·39	2·58	10	2
November	2·42	1·84	12	9
December	4·63	1·84	14	10

The summer rainfall, being mostly storm, produces little effect; the winter, not being merely local, at once makes itself felt. The average height at Diglis is

Rainless Period	No. of Days	Difference in Height of River		Height at Beginning and End of Period		
				Date	ft.	ins.
1887. February 5 to 16	11	7	2	{ 5	18	10
				{ 16	11	8
„ 24 to March 9	13	0	9	{ 24	11	9
				{ 9	11	0
April 5 to 21	16	1	0	{ 5	11	3
				{ 21	10	3
June 8 to July 4	26	2	4	{ 8	11	10
				{ 4	9	6
July 18 to 24	6	—	—	{ 18	9	6
				{ 24	9	6
„ 30 to August 12	12	0	3	{ 30	9	6
				{ 12	9	3
August 20 to 26	6	0	2	{ 20	9	8
				{ 26	9	6
September 17 to 26	9	0	9	{ 17	10	7
				{ 26	9	10

The figures seem to show that when the lowest level is reached, continuance of rainless periods has not much effect on the river. But, besides the mere absence of rain, so many other matters have to be taken into account that a deduction is impossible.

SATURDAY, SEPTEMBER 8.

The following Papers were read :—

1. *On Rolling Seamless Tubes from Solid Bars or Ingots, by the Mannesmann Process.*¹ By FREDERICK SIEMENS.

The author refers to the circumstance that steel and toughened glass, though specially suitable, on account of their high qualities and strength, for use in the arts, have been somewhat neglected owing to the difficulty of welding and cutting them. Attention is next drawn to the combination of strength with lightness which the tubular form admits of, and to the extensive use of tubes in construction which is likely to follow from a simple means of producing them. The different kinds of rolls hitherto employed which are classed as the longitudinal, circular and intermediate, are passed in review, and the process which forms the subject of the paper is then described.

In the Mannesmann Process, a certain relation between longitudinal and rotary motion is maintained, so adjusted for each material to be worked that a twist is imparted to the fibre resulting in great strength and toughness of the manufactured product. The following is the mode of manufacture: A bar is placed between conoidal rolls, where the diameter and therefore the velocity are least, and is gradually drawn forward into contact with those portions of the rolls which travel more and more rapidly. The rolls are so set that the space left between them for the passage of the bar decreases slightly, so as to cause a certain amount of material to be shifted. The action of the rolls preventing this material from being taken from the outside of the bar, it is consequently drawn from the interior, a hollow being first produced and then a tube.

A mandril may be employed to finish and smooth the interior and to enlarge

¹ Printed in extenso in *Engineering*, vol. xlv. p. 291.

the diameter of the tube. That the mandril is not required in the manufacture is proved by stopping the action of the rolls while the bar is passing through them, and breaking off the bar where the hollow is just commencing to form; the metal inside is found to be crystalline and bright, as before being cut there is a vacuum within the hollow, no air, of course, entering during the process of manufacture.

Specimens of tubes made out of Siemens open-hearth steel, which material is specially suitable for the purpose, were exhibited at the meeting; these show how the tube in the centre commences by a fracture of the metal, which widens out, and also the twist of the fibre having the appearance of a rope, which assists in giving the tubes their great toughness and resisting power.

2. *Gaseous Fuel.*¹ By J. EMERSON DOWSON, *M.Inst.C.E.*

At the York Meeting of the Association in 1881 the author explained an apparatus for making cheap heating-gas by passing steam and air through incandescent fuel. Since then the apparatus has been considerably improved, and the gas made in it has been much used, not only for driving engines but for heating in many industrial processes. The composition of the gas necessarily depends somewhat on the quality of the coal used and on the condition of the fire; the average composition is much the same, whether the gas is made at the rate of 1,000 cubic feet per hour in a small generator or at the rate of 15,000 cubic feet per hour in a large one. In 1881 it was necessary for gas engines to use five volumes of this generator gas for one of ordinary lighting-gas to develop the same power: since then some important modifications have been made in the Otto engines, and it is now necessary to use only four volumes. In 1881 only one engine of $3\frac{1}{2}$ horse-power had been worked with the author's gas, but since then a large number of engines have been worked with it, one indicating over 80 horse-power. For more than four years Messrs. Crossley, the English makers of the Otto engines, have used this gas exclusively at their works for an average power of 150 horse-power, and after a careful trial extending over thirty-five weeks they have found that the fuel consumption was only 1·3 lb. per indicated horse-power per hour. At these large works there is no chimney except for the blacksmiths' shop. Returns sent by eleven users of Otto engines working regularly in different places with the author's gas, and averaging 35 horse-power each, show an average fuel consumption of about 1·3 lb. per indicated horse-power per hour, which is less than half that required for the best steam engines of equal power. The results of other tests are given, and, seeing that all have been obtained under practical working conditions, the record is certainly satisfactory. Many letters have also been received testifying to the ease with which the gas plant can be managed.

The author considers himself justified in saying that gas-power is now fairly launched in competition with steam-power, and he thinks with the late Professor Fleeming Jenkin that eventually the former will to a great extent supersede the latter. The author also thinks it tolerably sure that even better results than those already recorded will be obtained when an engine is really designed to give the best effect with generator gas. It is well known that in the Otto engines each new charge of gas is diluted with a portion of the products of combustion from the previous charge, and this answers very well for ordinary lighting-gas. But as generator gas, such as the author's, has only about one-fourth the explosive power of the other gas, it is a disadvantage to dilute it with products of combustion, and he feels confident that sooner or later makers of engines will find it expedient to design all engines of large power specially for cheap generator gas. The best fuel to use for making the gas is anthracite, as it does not yield tar or other condensable products, and does not cake in the generator. Ordinary gas-coke can also be used with certain precautions.

Several instances are given of the use of this gas for heating of various kinds. At the Gloucester County Asylum it has been used daily for about five years. All the kitchen-work for the staff and inmates is done with it, and there is no

¹ Printed in *extenso* in *Scientific News*, Sept. 1888. Also by the author.

ordinary fire in the kitchen; about three hundred quartern loaves are baked with the gas every day at a cost of about one shilling only for fuel. The gas is also used for two 12 horse-power (nom.) Otto engines, which pump water and drive a dynamo for electric lighting. This gas is used on a large scale at the cocoa works of Messrs. Van Houten & Son, Messrs. Cadbury, and Messrs. Russ-Suchard & Co. Messrs. Onderwater & Co. of Dordrecht use it for heating the drying-chambers in their starch works. Messrs. Guittet of Herblay have for some years used it for making varnish, and they not only effect a considerable economy, but they avoid all risk of fire, which is a great consideration in varnish works. This gas is also used by the Société Nestlé for soldering their condensed-milk tins, and more recently it has been adopted by Messrs. Huntley, Bourne, & Stevens of Reading not only for soldering but for heating a large number of ovens in which japanned and varnished goods are stored. Messrs. Hillman, Herbert, & Cooper use this gas at their Coventry works and in Germany for brazing with blow-pipes the joints of bicycles and tricycles, as well as for enamelling. On the Continent several firms use this gas for singeing silk yarns and textile fabrics. It is also used by several linen manufacturers in the north of Ireland for stentering, which they formerly did with hot air. The cost of the gas somewhat depends on that of the fuel; but, speaking generally, the equivalent of 1,000 cubic feet of ordinary lighting-gas costs from sixpence to one shilling.

3. *The Shipman Engine.* By W. R. PIDGEON, M.A.

This motor is an automatic petroleum-burning steam engine, and has been designed by Mr. Shipman, of America, for use, either on launches or in houses, where a moderate amount of power is required. One of its essential points is that it is automatic, so that, when once steam has been generated in the boiler, practically no further attention is required beyond that of opening and shutting the steam valve whenever the engine is started or stopped, the fire, speed, and water-feed being so arranged as to attend to themselves.

The engine is simple or compound, as may be best suited to the work it has to perform, and is built upon the same frame as the boiler. This latter is composed of tubes about 18 inches long, which are screwed into a flat oblong chamber at one end and closed at the other, and is fired externally.

Two small aspirators or atomisers, taking steam from the boiler, suck up the petroleum, which is used as fuel, from a chamber below, and drive it into the furnaces in the form of a fine spray. A couple of torches ignite this spray as it passes inwards, and the flames produced by its combustion rush round and among the boiler tubes. The amount of steam and petroleum that is used by the atomisers is regulated by a diaphragm connected to a valve in the steam pipe that supplies them.

This diaphragm is exposed to the steam pressure on the one side, and is held down by a spring, loaded to a certain pressure, on the other, and moves upwards or downwards as the steam exerts more pressure than the spring, or *vice versa*. Its movement is conveyed to the valve by means of a rod, and it thus regulates the amount of steam passing at any moment to the atomisers. In this way the fire is made to vary inversely as the pressure in the boiler, and thus keeps the latter constant.

The petroleum is stored in a tank at any convenient distance from the motor, and is led to it through a pipe having a regulating valve in it. The water in the boiler is kept at a constant level by means of a float, connected to a tap in the suction pipe of the pump. This float is placed in a chamber, which is joined to the top and bottom of the boiler, and rises or falls with the level of the water. The movement is conveyed, through a stuffing-box and by means of levers, to the tap in the suction pipe, which it opens or closes as the water level changes.

The speed of the engine is kept regular by means of a governor, which works directly on to the excentric, and the lubricating of all journals, cylinders, and slides is performed by the ordinary sight-feed lubricators and cups, except that of

the crank-pin, which is effected by means of a centrifugal oiler attached to the crank disc. It may be seen from the foregoing that, when once steam is up, the fires, the water supply, the oiling, and the speed of the engine require no further attention. But, when first starting, a sufficient pressure is required in the boiler to work the atomisers, and for this a hand air-pump is provided. A few strokes of this pump will suffice to start the fires, and it is only necessary to pump slowly for five minutes to raise sufficient pressure of steam to keep them going, fifteen minutes in all being required to get steam up to 100 lbs. per square inch.

As regards the other requirements of small motors, the Shipman engine is compact, not heavy, and simple to understand, so that it neither requires much space, strong foundations, nor a skilled attendant. An engine developing $4\frac{1}{2}$ h.p. on the break uses 4.21 lbs. of petroleum per h.p.; and this, at 7d. per gallon, would give the cost of running at under 3d. per break h.p. per hour.

4. *On the Disengaging of Bouts, &c.* By E. J. HILL.

At the meeting of the Association in 1872 the author described a new hook for lowering and disengaging parcels, boats, and other objects, which shortly afterwards was very generally adopted, over 10,000 sets being at present in use.

After having considerable experience of this appliance the author in 1879 designed a simpler form, which may be described as a hook, shaped in the form of a horse's head, working in a link or shackle, and this in its turn has resulted in the form exhibited. One of the principles in view in all three systems is that the hook shall consist of a solid piece of metal, and not be altogether dependent upon the proper working of the parts added to it.

The new hook is a solid piece in the form of the letter G. Through the thick or back part of this G is a slot to admit of a small traverser having a U-shaped recess at one end which passes into the opening of the G, not only filling up the aperture but forming a perfect O. The upper part or actual hook of the G is curved round to such an extent that a ring or hook when engaged is safe to an angle of about 45° , and therefore it is impossible with a fair strain for the traverser to be moved; but, when this strain is taken off, the ring is inclined to fall into the U of the traverser, and of course is easily withdrawn. When it is required to prevent the traverser being moved in the end which projects through the back of the G a slot is made, in which a small flat locking key works. A pin or check is fixed on the traverser to control it in its movements. One of these hooks is fixed at each end of the boat pointing in the same direction, namely, towards the bow. By attaching a piece of wire rope to the two traversers the hooks are made to work simultaneously, as was demonstrated by means of models. This plan can be worked safely in several ways, either by the men in the boat, the coxswain of the same, the officer in charge of the lowering on board the ship, or automatically, in all of which cases the reliability of the working of the hooks is ensured.

The author concludes with a reference to the increased interest now being taken in all matters connected with the saving of life at sea.

5. *The old Orkney Click Mill.* By Professor A. JAMIESON, *M.Inst.C.E.*

The author, during a recent visit to the Orkneys, while inspecting one of the mountain burns that run down to Birsay Loch, came across a specimen of the old Click Mill, said to derive its name from the click-clack noise created by it when at work, which is supposed to have been introduced into these islands several centuries ago by the Norwegians. The interesting points about it are:—(1) It is the only remaining mill of its kind in Orkney; and (2) it is very like the latest and most perfect form of horizontal turbine in general conception and arrangement, for the water comes down near the centre on one side and flows freely away to the tail race. The farmer, Mr. Nicol Folster, stated that the mill had worked in its present position over 100 years. The construction and action of the mill were explained by means of a sketch and explanatory index. It consists of a horizontal

wheel connected direct to the moving or upper millstone by a vertical spindle, thus avoiding much friction.

The author concludes by pointing out how interesting it would be to ascertain whether another specimen of this mill is to be found in the British Isles, and why it has given place to the more complex vertical breast or overshot wheel, to again be reproduced in the most efficient form of turbine?

MONDAY, SEPTEMBER 10.

The following Papers were read:—

1. *On the application of Electricity to the working of a 20-ton Travelling Crane.*¹ By W. ANDERSON, M.Inst.C.E.

One of the travelling cranes in the foundry of the Erith Ironworks was originally constructed to be worked by hand, but preparations had been made to apply wire rope driving at some future time.

The crane is 39' 6" span, and consists of a pair of wrought-iron girders resting on end carriages running on an elevated line of rails. The gearing for hoisting and for longitudinal and cross traverse is secured on to the top of the main girders, the hoisting chain passes from the barrel at one end over a pulley at the other, then back to the pulleys in the cross traversing carriage, which runs between the main girders, through a falling block, and thence to an anchorage under the barrel at the extreme end of the main girders. By this arrangement the crane occupies a moderate height, and the hook can come within three feet of each wall.

The inconveniences and wear attending the employment of rope-driving gear induced the writer to try whether electricity might not be used with advantage. Messrs. Elwell Parker, of Wolverhampton, were communicated with, and these gentlemen undertook to supply the dynamo and a motor suitable for the peculiar requirements of a heavy crane. The dynamo, which was intended to give 50 ampères at 120 volts with 1,200 revolutions, was fixed in the main boiler-house of the works, and was driven by a small horizontal engine by means of a link belt. The leads from the boiler-house up to the conductor in the foundry are of 6 B. W. G. copper wire, while the conductor is formed of an angle-iron bar 2" x 2" x $\frac{1}{4}$ ", extending the whole 350-feet length of the shop, and has one face roughly ground and protected from rust by vaseline. The return current travels along one of the rails on which the crane runs. The motor, which is shunt wound, and constructed for 100 volts and 50 ampères, is fixed on the working platform of the crane beside one of the main girders. Its driving spindle carries a steel pinion which gears into a double helical spur wheel keyed on to a shaft which runs longitudinally on the top of the girder, and is connected by nests of three bevil wheels, with friction clutch connections to the three shafts which command the several movements of the crane, the means of using the hand-power being still retained.

Two sets of speeds are arranged for each of the movements, namely:

Hoisting	.	.	slow 3·4 feet per minute, fast 10 feet per minute
Cross traverse	.	.	" 25 " " " 105 " "
Longitudinal traverse	.	.	" 78 " " " 213 " "

To provide against undue strains upon the motor, an automatic magnetic cut-out is fixed on the crane, and for the purpose of varying the power and speed to meet the requirements of the foundry, a set of resistance coils is provided, governed by a special switch by means of which different resistances can be introduced into the armature circuit of the motor, or the current can be cut off altogether, but so that it must be done by steps, and not suddenly. The connection between the motor and the conductors is by means of brushes pressed against them by elastic

¹ Printed in extenso in *Engineering*, vol. xlv. p. 268.

attachments. The handles for operating the several movements, the break lever, the switch and the automatic cut-out, are all collected together, so that a single attendant can readily work the crane from one spot.

The crane was set to work in June last, and has continued to act satisfactorily ever since. The advantages are very great in the facility of adaptation, as it is so easy to transmit the power from any point. The main boilers being always under steam, the crane is available at a moment's notice. The duty realised is about 65 per cent. of the power developed in the driving steam-engine. As far as can be judged at present, there is no special wear to apprehend. The conductors act satisfactorily, though a considerable length is in the open air, and the dust, heat, and smoke of the foundry do not appear to affect the working.

When first proposed, the writer was not aware of the existence of any other electric crane, but he has since learned that Messrs. Mather & Platt, of Manchester, have had one working satisfactorily for some time, and that there is one also in France.

2. On recent Developments of the Cowles Aluminium Process.
By R. E. CROMPTON.

It is unnecessary to again describe the earlier stages of the Brothers Cowles' invention of the electric furnace. I confine myself to a description of such parts of the new plant which has been recently put down at Milton, near Stoke-upon-Trent, that I think will be of general scientific interest.

The experience in America at the works at Lockport, Ohio, showed conclusively that great economies were to be expected from increasing the size of the furnaces and the strength of the electric currents employed to work them; but no current larger than 3,000 ampères had been used up to the time that the Milton Works were planned.

Mr. Eugene Cowles came over to England to ascertain whether English makers of dynamo machines were prepared to supply one 60 per cent. larger than Mr. Brush's 'Colossus,' which had been made specially for them in America, and which was then the largest direct current machine in the world. He prepared his specification for a dynamo to give a current of 5,000 ampères at 60 volts, and eventually Messrs. Crompton's designs and tender were accepted.

The works were built near the Milton Station, on the North Staffordshire Railway; the boilers for generating the steam required are of the Babcock Wilcox type, and are provided with mechanical stokers; the steam-engine is of 600 h.p., and is a compound condensing horizontal tandem, made by Messrs. Pollit and

Wigzel of Sowerby Bridge. It is furnished with an exceedingly perfect centrifugal governor, which maintains the speed accurately at seventy-six revolutions in spite of very great fluctuations in the load. The electrical means of stopping the engine have been provided in the shape of Tate's electrical stop-valve, which may be described as an electro-magnet arrangement with the ordinary pushes for completing its circuit, which actuates a steam relay piston set to close the main-stop-valve. The fly-wheel of this engine is twenty feet in diameter and weighs thirty tons, and is geared to the pulley of the dynamo, so that the latter makes five revolutions for each revolution of the engine by rope driving gear consisting of eighteen ropes.

This engine is an extremely fine specimen of a modern steam-engine; it works so silently that a visitor standing in the engine-room with his back to the engine railings at the time the engine is being started, cannot tell whether it is in motion or not. The dynamo at first sight seems very small when compared with the steam-engine driving it, the fact being that it is dwarfed by the enormous fly wheel of the engine; it is only when one stands close to the plummer-block bearings that one realises the great size of the spindle, and of all the parts required to transmit the power to the armature coils.

The author was well aware when designing this machine that the mechanical strains on the spindle, core attachments, and winding were likely to be of an extraordinary nature. The following precautions were therefore adopted, and as events have turned out they have been more than justified. The spindle is of steel, 18 feet long, with three bearings, one being placed on either side of the driving pulley. The diameter is 7 inches in the bearings and 10 inches in the part within the core. This part in the original forging was 14 inches diameter, and was planed longitudinally, so as to leave four projecting ribs or radial bars on to which the core discs are driven, each disc having four key ways corresponding to these ribs. There are about 900 of these discs, the external diameter being 20 inches, and the total length of the core 36 inches. Originally this core was provided with thirty-two driving-teeth made of steel, each tooth riveted to sockets attached to eight of the core discs. It may here be mentioned that, as the working has shown, the strain on these driving-teeth was perilously near their factor of safety; their number has been doubled, so that now the tangential strains are borne by a very considerable percentage of the core discs.

The armature winding consists of 128 copper bars, each seven-eighths of an inch deep, measured radially, by three-eighths wide. These 128 bars are coupled up so as to form thirty-two conductors only; this arrangement has been adopted to avoid the heating from Foucault currents, which with one-and-a-half inch conductors would have been very considerable. The bars are coupled at the ends of the core across a certain chord, according to an arrangement patented by the author and Mr. Swinburne, which consists of crescent-shaped bars so formed that the whole surface is thoroughly exposed to the current of air passing through the armature; they are also somewhat shorter than those usually employed on drum-wound armatures. The bars are insulated by a covering of 'fiburite,' a material which has been recently introduced by Messrs. Crompton, and which will stand a temperature of 160° Cent. for long periods without the least discolouration, softening, or alteration of its mechanical and insulating properties. The commutator is 20 inches long, has sixty-four parts, and in addition to the usual tightening nuts at the two ends, is provided with a third tightening ring at the centre to prevent the tendency of such long commutator strips to spring when worn down thin. The current is collected by eight brushes mounted on a separate ring placed concentric to the commutator, and the current is led away from these brushes by a large number of thin bands of sheet copper strapped together into convenient groups.

The field magnets are of the horizontal double type, and were adopted by the author and Mr. Swinburne after a careful series of experiments, which convinced them that the fashionable single magnet form was very unsuitable for this kind of machine.

As this machine is virtually a series wound machine, the magnet coils each con-

sist of a few turns only of forged copper bars, one-and-a-half inches wide by one inch thick, forged to fit the magnet cores. There is no insulation other than mica wedges to keep the bars from touching the core.

The armature is ventilated by a current of air from a Schiele's fan, driven by a belt from the armature spindle. At 380 revolutions the armature can give 5,000 ampères at 60 volts, and the temperature of the hottest part, which is the end plates next the commutator, never rises beyond 70° Cent. Although this machine was designed to give only 5,000 ampères, yet, electrically speaking, it is capable of doing very much more, and in actual practice it has frequently to stand a current of 8,000 ampères for short periods. But, as will be shown later, when the furnaces are employed to produce ferro-aluminium there are frequently violent oscillations in the current, which would make it unsafe to employ an average current much in excess of 5,000. In fact, as has been stated above, it has been found necessary already to increase the number of driving-teeth in order to provide against the driving strains at the times of maximum current. When the machine was first tried the main circuit was unprovided with a cut-out, and there is no doubt that at this time the armature stood the test more than once of temporary currents exceeding 16,000 ampères. Since that time a safety cut-out has been provided, calculated to fuse at 8,000 ampères; this, probably the largest one that has ever been designed, consists of a framework carrying twelve lead plates, and these fuse at the calculated point in a most satisfactory manner, without any undue detonation or scattering of the molten lead.

Next to the cut-out comes the current indicator, which is simply a solenoid of nine turns through which the whole current passes. The core is attached by chain-gear to the pointers, of which there are two mounted on one spindle. One pointer and dial is placed in the engine-room, and the other in the furnace-room. The gearing of this spindle is calculated so that the range of the instrument up to 8,000 ampères extends over the entire circle of 360 degrees. The construction of the solenoid for this indicator is somewhat novel; it is cut out of a cylinder of cast copper by means of a parting tool in a screw-cutting lathe.

There are two furnace-rooms, each containing six furnaces, and the conductors, after leaving the current indicator, pass right across the two rooms at a height somewhat above the attendants' heads. The current is supplied to the furnaces as follows:—

Each furnace-pit consists of a long trough built of firebrick, the ends being closed by cast-iron pipes through which carbon electrodes are arranged so that they can be moved lengthways to and fro by the attendant in charge. It will be remembered that one of the main features of the Cowles' invention is the use of limed charcoal as a lining for their furnace; they thus obtain a highly refractory non-oxidising lining which is also a non-conductor of electricity, as the lime prevents the particles of carbon fusing together and thus forming a continuous conductor, which would otherwise short circuit the furnace and be consumed under the action of the current, instead of the latter performing its proper duty of maintaining the furnace contents at the required high temperature. The electrodes—each of which consists of nine carbon rods attached to a cast-iron head, mounted on a copper rod passing through the above-mentioned cast-iron pipes—are each provided with flexible copper-wire cable connections, having an attachment sliding along the conductors passing overhead and somewhat behind them. When it is desired to supply the current to any one furnace, the attachments are slid into position opposite it and clamped fast to the conductors; to start the furnace the electrodes are brought together so as to touch, and then separated until the whole of the contents of the furnace between them is an incandescent mass at the required high temperature.

The working of a charge in the furnace is carried out as follows: the bottom of the empty furnace is covered with limed charcoal; the electrodes are brought into position, and a former, or iron box without top or bottom, and of a size determined by the space to be occupied by the charge, is placed in the furnace; the ends of this sheet-iron box are arched out so that it can be dropped over the electrodes; the furnace lining of limed charcoal is then rammed up in the space

between the iron former and the furnace-walls. The space inside the box is filled with the furnace charge, which, when ferro-aluminium is to be produced, consists of a mixture of charcoal, bauxite, and iron-turnings, but when the cupro-aluminium is required granulated copper is substituted for the iron turnings.

When the furnace lining and contents are brought up to the proper level, the iron former is carefully lifted, much as a moulder draws a pattern from the sand; the cover is then luted on to the furnace, and it is ready for the electric current.

This at first is kept down to 3,000 ampères, but as soon as the charge is thoroughly warmed through, and the furnace contents become incandescent throughout, the current is increased to 5,000 ampères, and in about one hour's time the reduction is complete.

The reduced aluminium trickles through the furnace contents, and collects at the bottom below the electrodes, from which in the furnaces last constructed it can be tapped out continuously. Mr. Cowles believes that the temperature of the centre of the furnace is so high that both the reduced aluminium and the metal with which it is to be alloyed are vapourised and combine as a chemical compound when in this condition, being condensed in the upper and cooler part of the furnace, and thence passing down the sides to the bottom.

The working of the furnace when cupro-aluminium is to be produced leaves nothing to be desired; the current can be steadily increased from the commencement, and towards the end of the reduction it is extremely constant, so that the load on the boilers, engine, and dynamo is fairly steady throughout; but when making ferro-aluminium the conductivity of the furnace contents varies through very wide limits, and this brings heavy strains on both the steam-engine and dynamo, which must be met by correspondingly increased strength of parts. The chief feature of the process which strikes a visitor to Milton Works is the small number of men necessary to work the process: two men in the engine and dynamo room, one man at the boilers, and one boy to manipulate the electrodes of the furnaces, are all that are required for the active part of the operation; two labourers can easily charge and re-line the furnaces, and the remaining staff required for melting down, standardising, and casting into ingots the various classes of furnace products is correspondingly small.

From the experience already gained, the author sees no difficulty in designing and constructing engines and dynamos to supply currents of 15,000 or even 20,000 ampères, if such be required, for Cowles' furnaces of enlarged size. The electrical difficulties met with in the construction of this large machine have been comparatively small, whereas the mechanical strains have been unexpectedly great, and must be provided for by extreme solidity and massive construction.

Recent investigations made in America by Mr. W. J. Keep have shown that the use of ferro-aluminium is likely to be enormously extended when its properties in relation to cast-iron are thoroughly understood and appreciated by the engineering world. Mr. Keep is a gentleman who is well known in America, and his statements are entitled to be received with the utmost respect. We already knew in this country that the addition of ferro-aluminium to cast-steel or to ingot iron in such proportion that the finished casting will contain not more than one-thousandth part of aluminium produced extraordinary effects, in some cases reducing the melting-point 300° Cent., and in all cases imparting great fluidity to the metal, thus giving us sharp castings free from blow-holes; but it has remained for Mr. Keep to show us that the addition of an infinitesimally small percentage of aluminium to cast-iron insures perfect castings, freedom from blow-holes, and almost all the ills to which the ironfounder is subject. Mr. Keep's report is so very full that it is impossible to give any *résumé* of it here. I only call attention to it to show the extreme importance that ferro-aluminium is likely to assume in future engineering, and that as far as we know at present the perfected Cowles' furnace is capable of producing the desired material in any quantity and at a moderate cost.

3. *Electric Lighting in America.*¹ By Professor GEORGE FORBES, F.R.S.

The author drew attention to the directions in which this industry has been developed in America. The chief progress in central station work has been in three directions—(1) Arc lighting; (2) incandescent lamps with 3-wire system; (3) incandescent lamps with converters (Gaulard-Gibbs system). The number of arc lamps is now about 300,000. Every city in the States has some streets lighted by arc lamps. The author described the methods of distribution, and gave the reasons for slow progress in this country. There are at present $2\frac{3}{4}$ million incandescent lamps in use in the States. The author described the special features of the central stations, and drew conclusions as to the lessons to be learnt and applied to practice in this country.

4. *On a System of Electrical Distribution.*² By HENRY EDMUNDS.

The problem of the distribution of electricity has considerably occupied the attention of engineers, and several methods are in practical use, which may be classified under two heads—

1.—*Direct supply*, which has the advantages of simplicity, and the employment of currents of low tension; but the disadvantages of requiring large conductors, and being limited to short distances from the source of supply.

2.—*Secondary generators*, which are available over a larger area, and considerably lessen the size of conductors, but, on the other hand, require to be more carefully insulated and protected, to prevent danger to life and property from the high tension alternating currents employed.

Both these systems are dependent upon the regular working of the machinery at the central station; any stoppage plunging a whole district into darkness, to the great annoyance of consumers. To obviate this difficulty, secondary batteries have been suggested, which would act as reservoirs, always leaving a margin to be drawn upon in case of need. After reviewing the attempts which had been made at New York and Colchester to utilise secondary batteries for the distribution of electricity, and pointing out the causes of failure in each case, the 'Edmunds' System of Electrical Distribution,' in actual use by the Cadogan Electricity Supply Company in London, is described.

By this system, groups of cells are placed in various portions of the district to be lighted, each group being divided into a given number of sections. If the group be divided into four sections it is arranged that three of these sections shall be sufficient to supply the local demand, while the fourth is being charged by a line from the central station. At given intervals, the section which has been charged is removed from the main charging circuit, and switched into the local one, through which it discharges itself, its place in the charging circuit being taken by one of the other three, which, in its turn, is removed, and replaced by the next, and so on. So each section is kept well charged, the charge never being allowed to fall below a certain point. Thus the great desideratum is achieved, viz., *constant supply*, quite independent of any accident on the line or at the central station. These changes are brought about automatically by an instrument called a 'Distributor,' consisting of a revolving shaft carrying cams which, in their rotation, cause levers to rise and fall, and thus make and break the necessary contacts at the proper intervals. A polarised switch is attached, to prevent the current from entering the cells in the wrong direction, and also a voltage regulator, which keeps the batteries out of the charging main when they are fully charged, and connects them to it when they become exhausted, while a simple form of meter registers the amount of current consumed from day to day.

This system offers many important advantages. The durability of the cells is much increased, owing to the favourable conditions under which they work. The lamps give greater efficiency, through their being always run at an even pressure. The conductors are of moderate dimensions, and do not require to be enlarged

¹ Printed in extenso in *Electrical Review*, vol. xxiii. p. 275.

² *Ibid.* vol. xxiii. p. 284.

upon an extension of the work. The tension of the current employed is never high enough to endanger life or property; while the consumer has a reserve of electricity always at command, and is thus relieved from all anxiety regarding any sudden failure of the supply.

5. *The Measurement of Electricity in a House to House Supply.*¹
By W. LOWRIE.

6. *Electric Light applied to Night Navigation upon the Suez Canal.*²
By R. PERCY SELLON.

I. During the commercial crisis extending from 1878 to the early years of the present decade, traffic upon the Suez Canal increased largely. The number of ships passing through the Canal in 1878 was 1,593; this increased to 3,624 vessels in 1885, equal to a gross tonnage of nine million tons.

Increased traffic gave rise to inconveniences and resulted in frequent delays. Shipowners put pressure upon the Canal Company to afford facilities to cope with the increased traffic. In 1885 the average time occupied in passing through the Canal (eighty-seven geographical miles long) amounted to from forty to forty-five hours.

To meet the general demand the Canal Company introduced various improvements, and in the year 1884 commenced experiments to determine the practicability of navigation during the night by means of the Electric Light.

Owing to difficulties incident to the case these experiments occupied two years, resulting in an authorisation issuing from the Canal Company, in December 1885, permitting vessels of war and mail boats to navigate some portion of the Canal if provided with suitable Electric Lights.

In April 1886, the s.s. 'Carthage,' of the Peninsular and Oriental Steam Navigation Company, for the first time made the prescribed passage by night successfully, and was followed shortly by others.

The success of these results encouraged the Canal Company to extend the authorisation to vessels of all classes, and to throw open the whole length of the Canal to them. Thus, in February 1887, this authorisation was made public subject to certain regulations laid down by the Canal Company.

II. The plant to comply with above regulations consists of three essential parts:

1. Dynamo-Generator and engine.
2. Projector Search-Light to throw a beam 1,200 metres ahead of the vessel.
3. Automatic Electric Lamp capable of illuminating a circular area of 200 metres diameter around the vessel.

Accompanying diagrams illustrate the above plant and a vessel so fitted navigating the Canal.

The engine is of Brotherhood's three-cylinder type coupled direct to a Brush Victoria dynamo. The Projector Search-Light, fitted with spherical silvered mirror and diverging lens, is arranged to throw a beam diverging to angle of twenty degrees to a distance of 1,200 metres. The projector is fitted to a platform arranged to accommodate an attendant to manipulate the light, the whole being fixed to the stem of the vessel, forward and close to the water-line.

The automatic lamp is suspended from the masthead and lighted when passing vessels.

III. Figures are adduced to show the development of the Electric Light for this purpose: its advantages, economy, and probable future development are discussed.

¹ Printed in extenso in *Electrical Review*, vol. xxiii. p. 308.

7. *Electricity as applied to Mining.*¹ By FRANK BRAIN.

This paper is written from the mining engineers' standpoint, briefly sketching the known applications of electricity to mine-working up to the present date.

The writer regrets there is very little known to add to what has already been made public. He cannot but express surprise that a power which it is apparent has now passed the range of experiment, and is developing itself economically and efficiently, should not have been made greater use of than appears to have been the case hitherto.

The recommendations of the Mines Commission and the passing of the more stringent Coal Mines Act of 1887 have both stimulated mine managers to inquire into and recognise the advantages of electricity for blasting and lighting. By means of a small hand magneto battery and electric fuzes all the shot-firing in most of the fiery collieries is now done, the explosive used being one of the many lately introduced which, fired by an electric detonator, give off no flame. Dynamo machines at many pits are used for lighting the surface and main roadways of the colliery, and this current has also been used for the purpose of shot-firing, notably at Ynyshir Colliery, Rhondda Valley, South Wales. All the shots are fired in this way simultaneously while every man is out of the pit, thus putting loss of life beyond possibility. This adaptation, it should be said, however, is protected by a patent.

The adoption of the electric lamp in place of the well-known ordinary safety lamp is now very strongly advocated. There are several in the field, notably, the Swan and Pitkin, using secondary batteries, and the Scharschiff, using a primary battery. The South Wales Institute of Engineers, who with other kindred societies have lately had these and other electric lamps before them, have referred the matter to a Special Committee to inquire into and report upon. Several colliery engineers in South Wales are practically testing them—one, Mr. G. W. Wilkinson, of Risca, having several hundreds in daily use. So satisfied is he with their results that an order has been given for a still further number.

The applications of electricity to transmission of power are confined to a few collieries—so far as the writer knows, in Great Britain to three only, viz., Trafalgar Colliery, Forest of Dean; St. John's Colliery, Normanton; and Allerton Main Colliery, near Leeds. At Trafalgar, what was a very small pumping plant, started in December 1882, developed, by May 1887, into three sets of plant, doing the underground pumping of the colliery, and that at a saving of some 500*l.* per annum. At St. John's, a six horse-power set of pumping plant did such excellent work that a 33 horse-power set was put down in March last in another part of the colliery, and has since been in continuous work.

These extensions speak for themselves. In each case the power is conveyed by cables from the dynamo at the surface to the pumps placed at a considerable distance underground. At Allerton Main, very small quantities of water are being dealt with at inaccessible points. The power is supplied to the motors from secondary batteries charged at the surface, and conveyed to the required points in the colliery tubs or carts. A coal-cutter is also being driven by the same method.

On the Continent, underground haulage at Zaukeroda Colliery has been successfully and economically working since 1882, and also at Hohenzollern Colliery since 1884, the cost in each case being much less than by horses.

In America, where electric tramways are now numerous, the writer has been able to obtain particulars of but one application to mining: this is a railway on the same system as the Zaukeroda. The electric locomotive receives the current from an overhead conductor, the return current to the dynamo passing through the rails. It is at Short Mountain Colliery in the Wiconisca mines, and has been working satisfactorily since April 1887.

There has lately been put in operation at Big Bend, on the Feather River, Butte Co., California, the most stupendous set of electric mining plant, so far as the author knows, in existence. A large river has been tapped, and with a fall of three hundred feet it gives hundreds of horse-power by means of Pelton wheels.

¹ Printed in *extenso* in *Electrical Engineer*, vol. ii. (N. S.), p. 310.

These actuate electric generators, from which the currents are sent along a circuit of eighteen miles, driving Sprague motors at fourteen different points where power is required in a mining district for pumping, hoisting, &c.

The falls at Roaring Fork, Grand River, are utilised for driving an electric generator, from which the power is conveyed across country over a mile to Aspen Mines, Colorado, where a 10 horse-power Sprague motor is driving the mine machinery, replacing steam power with considerable economy.

A gold mine in New Zealand has recently been made valuable by transmitting the power from a waterfall two miles away. The conductors, supported on poles, are carried direct over the mountains, two thousand feet intervening between the fall and the mine. Obviously, where water power can be thus applied, the saving as compared with using fuel is considerable, especially in metal or diamond-mining districts, where coal is expensive. The ease with which the power can be conveyed over hill and dale and into the intricacies of the mine is also a factor of no mean importance.

It will be seen from the above how meagre are the results in transmission of power up to the present, and yet in every case where it has been adopted it has proved economically successful.

Possibly in fiery mines some are afraid of the sparks. There is no danger whatever on this head, as all the machinery can be enclosed in an air-tight chamber. It may be that want of familiarity hinders others; they fear to embark capital in plant of which they cannot speak from their own experience.

The failures in the history of electric lighting have no doubt prejudiced some, and they look upon the electric light and all akin to it with suspicion. The writer will be amply repaid if he can by means of this brief paper so interest some mining engineers as to cause them to take up the matter for themselves. He is satisfied that, under many conditions common in colliery working, electricity can and will be applied successfully and economically.

8. *Miners' Electric Safety Lamps.*¹

By NICHOLAS WATTS, Assoc. M.Inst.C.E.

After referring briefly to the but partial success attained in modifying miners' oil-lamps to adapt the same to the currents now obtaining in collieries, and noticing the apparent suitability of the incandescent lamp as a substitute, the author described the following miners' portable electric safety lamps, some of which he exhibited:—

The Swan Lamp.—Secondary battery. Four cells grouped together in a block of gutta-percha which is enclosed in a wooden case. The elements are lead oxide and lead. Luminosity, 1 to 1½ candle for ten hours' duration. Weight, 7 lbs. Price, 27s. Cost of maintenance, 3½d. per week. In extensive use in South Wales.

The Schanschieff Lamp.—Single liquid primary battery. Four zinco-carbon cells, the carbon non-porous. The peculiar novelty is the nature of the exciting liquid, which is a solution of the basic sulphate of mercury, about 33 per cent. of the salt being held in solution. The solution is sold at 4s. per gallon, of which 3s. 7d. is allowed for the same quantity of the spent liquid with its solid residue and free mercury precipitated by the cells. Luminosity (with reflector), 2 to 3 candles for nine hours' duration. Weight, about 5 lbs. Price, 30s. Cost of maintenance, 3¾d. per week. Tested at Cannock Chase, Mardy, Merthyr, and elsewhere.

The Pitkin Lamp.—Secondary battery. Four cells. Luminosity (with reflector), 4 to 5 candles for ten hours' duration. The lamp is fitted with a switch and resistance to regulate the expenditure of the electro-motive force, which, if allowed to act without check, would, when the battery was started, destroy the filament. Weight, 8 lbs. Price, 2l. 2s. Used at Llwynypia, Ocean Colliery, Treviky, and elsewhere.

The Walker Lamp.—Primary battery. Three carbon-zinc cells in a strong

¹ Printed in extenso in *Electrical Engineer*, vol. ii. (N. S.), p. 226.

brass cylinder attached to an outer case of brass or copper. The exciting liquid is a mixture of bichromate of potash, nitric acid, and sulphuric acid. Luminosity (with a reflector) sufficient to enable newspaper print to be read at a distance of twelve feet, for ten hours' duration. Weight, 7 lbs. Price, by the gross, 32s. Cost of maintenance, 1d. per day.

The Portable Electric Syndicate's Lamp.—Secondary battery. Luminosity (without reflector), $1\frac{1}{4}$ candle for ten hours' duration. Weight, 4 $\frac{1}{4}$ lbs. Price, one guinea. The lamp is fitted with an automatic arrangement in connection with the incandescent lamp, whereby if an outer casing of toughened glass be broken the current is cut off to prevent explosion of fire-damp.

The Vaughton Lamp.—Secondary battery. The electrodes are wedged tightly in the cell, rendering the battery so compact that it may be subjected without injury to much rough usage. The lamp weighs 5 lbs. It takes six hours to charge. The working cost is estimated at 1d. per day. The electrolyte used is sulphuric acid diluted with eight times its volume of water, and is renewed twice a week. One shilling's worth of acid suffices for 100 lamps for one week. The price is from 25s. to 27s. 6d.

The author concluded by referring to the questions of primary *versus* secondary batteries, and considered the position of the light on the lamp case as not finally settled.

9. *On an Automatic Fire-damp Detector.* By JOSEPH WILSON SWAN, M.A.

At the last meeting of the Association, the author communicated to this Section a description of a fire-damp detector and meter, designed, more especially, to be employed as an appendage to electric safety lamps and exhibited a working model of the combination.

The object of that apparatus was to provide means by which the manager or one of the overseers of a colliery could, by making tests in various parts of a mine, ascertain, with a considerable degree of exactness, whether or no fire-damp is present, and, if it be, in what proportion. That apparatus fulfilled its purpose very well; it was accurate and sensitive, so much so that if only the one-tenth of 1 per cent. of fire-damp existed in the air it was clearly shown.

But it was not sufficiently simple to allow of its being made an adjunct to every lamp, nor was it automatic in its action. It therefore appeared desirable, if possible, that these deficiencies should be met or complemented by a simple and automatic apparatus, suitable for attachment to every electric safety lamp, or at least to all those used where gas is likely to be found. Such an apparatus he has the honour to bring under the notice of the members. The primary principle of its action is the same as in Liveing's well-known gas indicator, in which difference of temperature in two similar electrically heated platinum wires (one exposed to the air to be tested, and the other enclosed in a glass tube) caused by the combustion of fire-damp in contact with the exposed wire.

In Liveing's apparatus the quantity of gas present in the air is estimated by the degree of difference in the luminosity of the two wires.

In my apparatus use is made of the difference of temperature arising in the manner described, but so as to cause movement in a column of mercury, and through that the interruption of the electric current which lights the lamp; therefore the lamp provided with this apparatus goes out just as an ordinary safety lamp does when placed in air contaminated to a certain extent with fire-damp.

In another form of the apparatus, difference of temperature in the indicator wires causes the free ends of a pair of thermoscopic metallic spirals to separate, and by separating to interrupt the electric current which lights the lamp connected with the indicator, and in that way to bring about the extinction of the light.

The new gas detector is therefore distinct from what has hitherto been proposed in its acting automatically upon the lamp, so as to extinguish its light.

It takes the form of a small circular metallic box, fastened upon the outside of the lamp case; the box contains a differential thermometer.

In the first-mentioned form of the apparatus it consists of two glass bulbs (con-

taining air), united by a U-shaped tube containing mercury in the bend, and having sealed into it two thin platinum wires whose inner ends are in contact with the mercury, one deeply and the other slightly submerged beneath its surface. There passes through the bulbs the two tubes (one open and the other closed), containing the two platinum wires, difference in the temperatures of which determines the action of the apparatus.

The current which passes through the lamp filament traverses also the indicator wires, and the wires in contact with the mercury; it will therefore be easily understood that, in the *absence* of fire-damp, as the wires contained within the thermometer bulbs will be equally hot, there will be no movement of the mercury, and that in the *presence* of fire-damp, as the exposed wire will become hotter than the enclosed wire, the air in the two bulbs will be unequally heated, and consequently the mercury will move away from the hotter bulb, and if its movement is sufficiently great to uncover the end of the least submerged wire, the circuit will be broken, and the light will go out. A switch is provided to enable the broken circuit to be remade, and the lamp lighted after the indication has been given.

The indicating wires are so short as not to consume a large proportion of the energy of the battery. This is the more necessary as it is intended that the current shall continually pass through them during the time the lamp is in use.

The other form of the apparatus to which he referred is similar in principle to that described, but instead of the differential *air* thermometer, use is made in it of a differential *metallic* thermometer, constructed on the principle of Immisch's pocket thermometer. In this case the thermoscopic part of the apparatus consists of a pair of helical tubes of oval section filled with liquid.

The pair of helices are in every respect alike except that one is a right-hand screw and the other a left; they are arranged one over the other with their free ends lightly touching, so as to be in electrical contact with each other.

Variation of temperature, acting equally upon both spirals, does not disturb the contact, but if one helix be heated more than the other, there will be separation of the free ends and breaking of the electrical contact. In adapting these to the purpose of the detector, the enclosed platinum wire is fixed in the axis of one helix, and the open wire in the axis of the other. The electrical connections are so made that normally the current from the lamp battery passes through the lamp, the exposed and enclosed platinum wires, and the helices; and, as in the other form, there is a switch to close the circuit and relight the lamp when it has been extinguished by the action of fire-damp.

The apertures by which the air gains access to the exposed platinum wire are carefully guarded by wire gauze; and they can be closed entirely when, by the going out of the light, there is evidence of the presence of fire-damp.

TUESDAY, SEPTEMBER 11.

The following Papers were read:—

1. *An improved Seismograph.* By E. A. COWPER, M.Inst.C.E.

In order to register the motions of the earth, north, south, east and west, it is of course necessary to have a heavy weight as little as possible affected by the motion of the earth; parallel motions, or 'compound pendulums,' have been used with good effect, but a simpler and more effective plan would be to place a heavy flat weight on a plate of glass with three small 'steel bicycle balls' below, resting on another flat or slightly hollowed plate, so that when the vibrations of the earth ceased, the weight would slowly return to its normal position. In place of glass plates, ground porcelain or metal plates might be used. The weight might be brought back to its normal position by a light pendulum, and then all the plates might be *flat* and of *common plate-glass*. Then two levers, acted on from the centre of gravity of the weight, and multiplying the motions, would register on long strips

of paper the vibrations, north and south, east and west; the paper, of course, being driven by clockwork, and allowed to start as soon as the vibrations of the earth commenced.

Then the vertical vibrations (which have always been the most difficult to obtain a record of) can be very thoroughly ascertained and recorded, by the following simple arrangement.

A light sheet-iron or steel tube, closed at the top like a small 'gasholder,' is inserted in a tank of quicksilver, the centre space inside the 'gasholder' being occupied by an empty tube, so as to reduce the weight of quicksilver very materially; then on exhausting the 'gasholder' with a 'Sprengel pump,' the tank will rise, owing to the pressure of the atmosphere below it, until the column of mercury balances the atmosphere; thus the weight of the tank and mercury in it being in fact supported by the *atmosphere*, and the 'gasholder' being attached to the earth, the 'gasholder' may rise or fall and yet scarcely affect the tank in any way, and a rod from the tank to a multiplying lever, attached to the earth and recording apparatus, will record the vertical vibration on a strip of paper moved by the clockwork.

The clock will be kept always going, but the paper will be started only when there is motion to be recorded.

The attendant, on leaving the apparatus, will throw in a small catch to stop the paper rollers, and the first motion of either of the levers will be made to throw out the said catch, and so start the paper. The clock will be arranged to record time by pricking the paper at certain intervals.

2. *The Friction of Metal Coils.* By Professor H. S. HELE SHAW and E. SHAW.—See Reports, p. 540.

3. *Steam Engine Diagrams.*¹ By M. F. FITZGERALD.

Diagrams were exhibited showing the weight of saturated steam present throughout the stroke. In a four-cylinder compound the apparent weight of steam supplied was in the four cylinders—

1st cylinder	. . . 1.47 lb.		3rd cylinder	. . . 1.32 lb.
2nd „	. . . 1.23 „		4th „	. . . 1.24 „

In a Corliss engine re-evaporation took place up to about 2/3 stroke, when the increase in weight of saturated steam amounted to 47 per cent. of the steam at cut-off.

In two compound pumping-engine diagrams there was in one case an increase, in the other a decrease, in the steam apparently supplied to the second cylinder. An intermediate heater is used in both of these engines.

When the action of the cylinder sides is such as to produce a rise, followed by a fall, in the weight of steam, then at the point where there is neither evaporation nor condensation the proportion of dry steam in mixture present is given (Cotterill, 'Steam Engine Considered as a Heat Engine,' pp. 195-6) by

$x = \frac{T}{1450}$, approximately a half; hence at this point the working substance is known, and theoretically the heat supply of the engine can be inferred from the indicator diagram alone.

During compression the cylinder sides nearly always act in this way, and are practically equivalent to a weight of water equal to that of the steam in clearance.

During lead extremely rapid changes of temperature take place; the rate of transmission of heat to the cylinder surfaces rises as high possibly as 150 heat units per square foot per second, confirming Professor O. Reynolds's experiments on surface condensation, and is much higher than is estimated by Cotterill ('Steam Engine,' pp. 248-9).

¹ Printed *in extenso* in *Industries*, vol. v. p. 333.

4. *The Efficiency of Steam at High Pressures and the Carnot Theorem.*¹
By W. WORRY BEAUMONT, M.Inst.C.E.

The object of the author of this paper is to show that the Carnot theorem as expressed by the equation $E = \frac{T-t}{T}$ is inapplicable for the calculation of the efficiency of steam as used in a steam-engine cylinder. It is shown that the work done by expanding steam bears no relation to the fall in temperature due to fall in pressure, and that with steam at pressures between 350 lbs. and 50 lbs. per square inch the work done by expansion varies from 692 foot-lbs. to 1,050 foot-lbs. per degree of fall in temperature.

The argument leads to the conclusion that pressures higher than those now used can be very advantageously employed.

When the exchange of heat due to difference in latent heat, total heat, and temperature at the different pressures is taken into account, the difference in favour of the high-pressure steam becomes much greater. An explanation is afforded of the great efficiency of triple stage expansion engines as compared with the lower pressure simple engines. The steam in the steam-engine must be considered with reference to that part of its history which is comprised between its admission to the cylinder and the instant of exhaust, and with reference to the heat used, not to the fall in temperature. By increasing the pressures used, an extra number of stages of expansion may be obtained at a small extra expenditure of heat in the boiler. The difference ΔH between the total heat of steam at 300 lbs. and at 250 lbs. is under five units, but the work done by expansion from 300 lbs. to 250 lbs. is 12,240 foot-lbs. or about 2,400 foot-lbs. per unit of heat employed in raising the pressure from 250 lbs. to 300 lbs. The work done per unit of heat disappearing on expansion for each stage of 50 lbs. is given in a table.

5. *Revolving Sails, or Air-propellers.*² By H. C. VOGT.

If ships could be towed instead of propelled by means of the ordinary propellers, which disturb the stream lines round the ship, a saving on the average of 40 per cent. in coals and engine-power would be gained; the screw especially sucks the sustaining water from the ship, causing its resistance to be augmented in the same proportion; the thrust of the propeller must therefore exceed the net resistance of the ship by this amount. This excess in the resistance can only be reduced by destroying the shape of the ship. Formerly the length of ships was three to four times the breadth, now it is ten times the breadth. Both these proportions cannot be correct, and it must be remembered that the weight of the hull increases with the second power of the length, the middle section remaining unchanged. The screw-propeller increases, further, the change in the trim of the ship when the speed increases, also causing an increased resistance; and this ill-effect can only be counteracted by giving the driving thrust considerably above instead of below the centre of gravity of the ship. •

Air-pressure on large canvas areas has been used from time immemorial: the author only proposes to use comparatively small driving areas, radiating from an axis parallel to the keel, and supported between two low pillars. The external appearance of such an air-propeller is similar to that of a screw-propeller; but the wings of the air-propeller are broadest near the circumference, and they are made of thin sheet-steel. Rotated quickly in the elastic air, a rarefaction on the front side of the wings is created, and the consequent difference in pressure constitutes the thrust, which, with a given engine-power, is quite as high as with the common screw in inelastic water. To create such a rarefaction, speed rather than area is required. Take, for instance, the wings of a wild swan, which possess 25–28 times the area of the web feet, while the thrust yielded from the wings is many times that yielded from the web feet. Suppose the horizontal water-resistance when the swan swims fast to be four pounds; when it flies the horizontal resistance may perhaps also be

¹ Paper is published *in extenso* in *Industries*, vol. v. No. 119.

² Printed *in extenso* in *Industries*, vol. v. p. 335.

four pounds, and in addition to this is the weight (35 lbs. for a large wild swan), and this weight is only supported by every downstroke of the wings. The rarefaction on the top side of a wing is produced by the suction from the air-currents passing its rigid fore-edge, just as the rarefaction is produced in a funnel by the wind passing over its edge: a difference in pressure corresponding to 30 lbs. per square foot may occur on windy days. The other important factor in producing a rarefaction on the lee side of a rotating surface is centrifugal force, as explained in the paper. These considerations will serve to explain why the area required for an air-propeller has no connection with the ratio between the specific gravities of air and water, the only means of moving a large quantity of air so as to create a momentum being the rarefaction, or storm centre, in front of the propeller. To create a sufficient rarefaction, the area of an air-propeller ought to be 12-14 times, and the diameter 3-4 times, that of the ordinary water-propeller; but less than this for large vessels, as a natural consequence of the mathematical laws governing these matters. The losses of a propeller in water are—(1) loss by friction; (2) loss by throwing out water in wrong directions; (3) loss by blows. Thanks to the perfect elasticity of air, there will only be the two first-named kinds of losses in that medium. If, for instance, equal weights of air and water moving at the same velocity strike a plane, the pressure from the air will be twice that from the water; and this can also be recognised from the resistance of air, which is about $\frac{1}{400}$ th part of the resistance of water, although the ratio between their specific gravities is $\frac{1}{770}$. An air-propeller is therefore not efficient as a fan, but very efficient as a propeller. If an air-propeller is mounted on a boat and pulled by the power of a man, the boat receives much greater speed than when the same man applies his force in the same boat furnished with a water-propeller. But this difference between the thrusts which a man can yield with an air-propeller and a screw is, of course, not great. The same winds which are useful for ordinary sails are also a gain for rotating sails; that is, 75 per cent. of the winds augments the thrust of an air-propeller, and the energy of the natural wind is taken advantage of when the pitch is changed in accordance with it. When the wind 'straight against' equals the speed of the points of effort of the rotating sails, the thrust of the air-propeller is decreased nearly 60 per cent., or just the same as the thrust of gaff sails is reduced when from having the wind on the beam the course is changed until four points from the wind. Now it happens once a month that a strong wind is actually so straight against the course as to reduce the thrust by 60 per cent. for a propeller with manual power. On a 1,000-ton ship the speed of the points of effort of its air-propeller would be over 150' per second, and no hurricane would be able to reduce its thrust by 60 per cent., and 3.5 points from the hurricane the thrust of the air-propeller would be greater than in a calm. As compared with this the increased resistance caused by the screw is constant.

Details of experiments on a large scale, as well as of the formula for finding the area and speed of an air-propeller, are given in the paper.

6. *A new Sphere Planimeter.* By Professor H. S. HELE SHAW.
See Section A, p. 584.

WEDNESDAY, SEPTEMBER 12.

The following Papers were read:—

1. *Underground Railway Communication in Great Cities.*
By Colonel ROWLAND R. HAZARD.

Perhaps the most important physical problem, growing out of the concentration of great populations in limited areas, is the construction, maintenance, administration, and uses of the public streets. These, absolutely indispensable for purposes

of ordinary traffic, fulfil many other requirements of public necessity or convenience, but should be so constructed as to provide for many others of capital importance, growing out of the multiplying wants incidental to the demands of modern civilisation.

The main thoroughfares of traffic should be reconstructed, substantially upon the plan of superficial subways and galleries, illustrated by a model and sketches shown. Between the lines of curb the substance of the street should be removed to a standard depth of twelve feet, and the excavation so made replaced by four centrally placed subways, the two interior ones being devoted to rapid transit or fast railway trains, operated at great speed between few stations. This form of railway service, essential to economy of time and the proper development of suburban population, is not now performed at all in any great city, the two exterior subways being devoted to 'way' or slow trains, operated rapidly between frequent stations, for the convenience of every district on the line for shopping, and also for supplementing the more rapid long journeys of the express line.

These railways should be operated by electric motors and solid trains, specially devised for the service, and embodying provisions for safety and comfort to a degree which apparently precludes the possibility of serious accident. On either side of these centrally disposed railway subways are placed continuous galleries, calculated for the housing, inspection, replacement, and repair of all pipes and wires of communication, sewers for local service, water mains and supplies, gas mains and service pipes, steam service pipes, pneumatic power, post, parcel, refrigerating and time tubes, electric wires for arc and incandescent lights for street and private use, for power, signals, telegraphs, telephones, &c., and all other essentials or conveniences which are more profitably generated or produced at some central station, and can be distributed or served only through the public domain, overhead or underfoot, and which from the want of such common accommodation are now used—if at all—to a limited extent, at great cost and inconvenience to the authorities, the corporation, and the public.

It is also imperative that the whole subway system should be adequately supplied with fresh air in movement, so that ventilation shall be as perfect as in the best arranged dwellings. This could be effected by closing the railway subways from any communication with the surface of the streets except through the station doorways, and ventilating the stations by shafts supplied with electric exhaust fans, placed in the rear of the entrance buildings, the supply of fresh air being derived from similar shafts placed in the rear of the opposite building; by this means the air of the stations will be absolutely renewed as frequently as required. The railways form open cylinders from station to station, and the trains, being of approximately the same cross-section, constitute loose pistons always moving in the same direction. The effect is the establishment of a ventilating current within the subways dependent for its force upon (1) the approximation of cross-sections, (2) the speed of the trains, and (3) the integrity of the tunnels or subways.

As the products of artificial combustion will be excluded as far as possible, the requirements of ventilation are reduced to a minimum and perfectly performed.

Reference is made to a new material, 'ferflax,' composed of braided steel wire and flax fibre, chemically treated under hydraulic pressure, devised for the wall panels of the subways and for the construction of the railway carriages, a compound building material not unlike horn in character, having a strength and flexibility somewhat exceeding steel wire netting, a toughness approximating to horn, non-fragile and unbreakable by bending, and not liable to shatter under shock.

The necessity for fast intramural travel is illustrated by the fact that the population of the City of New York increased from 1865 to 1885 (twenty years) 50 per cent., while the traffic increased 262 per cent., demonstrating that traffic increases out of all proportion to population; and that the fast travel increases at the expense of the slow, is clearly proved by the extraordinary increase on the elevated roads, which for the single year 1887 amounted to the incredible number of 43,853,641 passengers, being 33 per cent. more than the total increase of all lines for the previous year, and actually more than the total increase for that year.

The adoption of this system for the streets of every great city would effect an economic revolution. There would be rapid communication between distant points within the metropolitan areas; there would be rapid communication between frequent stops for the convenience of local traffic and shopping; the streets would be brilliantly lighted by electricity; every house on the line would have access to gas, steam, water, the telephone, telegraph, pneumatic tube, electric light, and compressed air at will. Small industries would flourish because small and cheap power from remote stations would be everywhere available, while the surface of the streets could be maintained in a perfect state, with the minimum of cost, and with complete immunity from disturbance other than for the repair of worn surfaces.

2. *Transmission of Motion and Power.* By J. WALTER PEARSE.

The flexible clutch is the first practical outcome of the mechanical combination devised by M. R. Snyers, of Brussels, and described by the author in a paper on the 'Communication of Motion between Bodies Moving at Different Velocities' during the Manchester meeting of last year. While each of the fibres into which the mass of one of the two bodies is split up acts separately and individually, causing no shock on contact, their sum exerts a considerable mechanical effort. About a dozen flexible clutches and combined fast and loose pulleys are now in operation, transmitting motion to dynamos, emery grinders, spinning machinery, sewing machines, thus preventing that breakage of the beam or arm of the latter which frequently occurs on power being applied in the ordinary manner. The amount of power transmitted is just that for which the clutch or pulley is calculated, the two parts slipping when that power is exceeded by the motor, or on an excess of power being demanded by the machine, this property being useful in cases of letting out power on hire. When, however, a clutch or pulley is of a maximum capacity, any lower amount of power may be transmitted by regulating the degree of penetration of the fibres between the corrugations of the other disc. Experience shows that wear of the fibres, even when there is a considerable amount of slip, is negligible, the corrugated disc being made of softer material; and this fact shows the applicability of the principle to brakes of various kinds, which would exert a retarding force equal to three or four times that employed to apply them, whereas ordinary brake blocks never utilise more than 25 per cent. of the power exerted.

3. *An Annual Winding Clock, with Torsion Pendulum.*¹ By W. H. DOUGLAS.

There is no change whatever in the wheel-work or main spring of an eight-day lever clock except in the balance. The balance is removed, and in its place a *lever* is fixed to the staff carrying the roller pin, which unlocks the lever escapement and receives an impulse at each beat in the usual way, the additional lever imparting impulse to a tooth attached to the pendulum, thus inducing torsion at each beat of the clock. The regulating is effected by increasing the weight of pendulum to make it lose, or decreasing the weight to make it gain; it is also regulated by means of a French sliding curb, moved by a screw to the right or left, as desired, to make it go faster or slower without stopping the clock.

The escapement may be described as a *frictionless pendulum*. The impulse, given direct across the line of centres, as in the chronometer, is independent of oil, and, becoming detached at each beat, the isochronal property of the pendulum is not deranged by friction of any kind whatever.

The cost of manufacture is precisely the same as in producing an eight-day timepiece.

¹ See *Engineering*, vol. xlv. p. 413.

4. *A new form of Air-compressor for Variable Pressures.*¹

By H. DAVEY, M.Inst.C.E.

This is an air-pump capable of automatically maintaining a constant resistance when pumping against an increasing or decreasing pressure.

One of its applications is that of compressing air for storage purposes.

It is evident that if an ordinary air-pump be made of sufficient capacity to take the full power of the engine employed to drive it at the minimum pressure, it will be too large for the increasing pressure; and, on the other hand, if the pump be made small enough for pumping against the maximum pressure, it will only take up a portion of the power of the engine at the lower pressures.

The problem then is to construct an air-pump which shall work with a constant resistance against increasing and decreasing pressures. It is evident that if the weight of air per stroke of the air-pump could be made to vary inversely with the varying pressures against which the pump works (in proper proportions) then the engine would have a constant resistance, and its full power might be employed during the whole of the operation. This is effected by mechanical means, described and illustrated in the paper. The resistance of the pump governs the engine. The engine runs without a throttle valve and with varying steam pressures at a constant speed, always fully utilising the full power available, and thereby doing the work in the shortest time with the greatest economy of power.

5. *On controlling the direction of Rotation of a Dynamo.* By A. WINTER.

¹ See *Engineering*, vol. xlv. p. 413.

SECTION H.—ANTHROPOLOGY.

PRESIDENT OF THE SECTION—Lieut.-General PITT-RIVERS, D.C.L., F.R.S.,
F.G.S., F.S.A.

THURSDAY, SEPTEMBER 6.

The PRESIDENT delivered the following Address:—

HAVING been much occupied up to within the last week in my own special branch of anthropology, and in bringing out the second volume of my excavations in Dorsetshire, which I wished to have ready for those who are interested in the subject on the occasion of this meeting, I regret that I have been unable to prepare an address upon a general subject, as I could have wished to do, and am compelled to limit my remarks to matters on which I have been recently engaged. Also, I wish to make a few observations on the means to be taken to promulgate anthropological knowledge and render it available for the education of the masses.

Taking the last-mentioned subject first, I will commence with anthropological museums, to which I have given attention for many years. In my judgment, an institution that is dedicated to the Muses should be something more than a store, it should have some backbone in it. It should be in itself a means of conveying knowledge, and not a mere repository of objects from which knowledge can be culled by those who know where to look for it. A national museum, created and maintained at the public expense, should be available for public instruction, and not solely a place of reference for *savants*.

I do not deny the necessity that exists for museum stores for the use of students, but I maintain that, side by side with such stores, there should in these days exist museums instructively arranged for the benefit of those who have no time to study, and for whom the practical results of anthropological and other scientific investigations are quite as important as for *savants*.

The one great feature which it is desirable to emphasise in connection with the exhibition of archæological and ethnological specimens is evolution. To impress upon the mind the continuity and historical sequence of the arts of life, is, without doubt, one of the most important lessons to be inculcated. It is only of late years that the development of social institutions has at all entered into the design of educational histories. And the arts of life, so far as I am aware, have never formed part of any educational series. Yet as a study of evolution they are the most important of all, because in them the connecting links between the various phases of development can be better displayed.

The relative value of any subject for this purpose is not in proportion to the interest which attaches to the subject in the abstract. Laws, customs, and institutions may perhaps be regarded as of greater importance than the arts of life, but for anthropological purposes they are of less value, because in them, previously to the introduction of writing, the different phases of development, as soon as they are superseded by new ideas, are entirely lost and cannot be reproduced except in imagination. Whereas in the arts of life, in which ideas are embodied in material forms, the connecting links are in many cases preserved, and can be replaced in their proper sequence by means of antiquities.

For this reason the study of the arts of life ought always to precede the study of social evolution, in order that the student may learn to make allowance

for missing links, and to avoid sophisms and the supposition of laws and tendencies which have no existence in reality.

To ascertain the true causes for all the phenomena of human life is the main object of anthropological research, and it is obvious that this is better done in those branches in which the continuity is best preserved.

In the study of natural history, existing animals are regarded as present phases in the development of species, and their value to the biological student depends, not so much on their being of the highest organism, as on the palæontological sequence by which their history is capable of being established. In the same way existing laws, institutions, and arts, wherever they are found in their respective stages of perfection, are to be regarded simply as existing strata in the development of human life, and their value from an anthropological point of view depends on the facilities they afford for studying their history.

If I am right in this view of the matter, it is evident that the arts of life are of paramount importance, because they admit of being arranged in cases by means of antiquities in the order in which they actually occurred, and by that means they serve to illustrate the development of other branches which cannot be so arranged, and the continuity of which is therefore not open to visual demonstration for the benefit of the unlearned.

It is now considerably over thirty years since I first began to pay attention to this subject. Having been employed in experimenting with new inventions in firearms, submitted to H.M. Government in 1852-3, I drew up in 1858 a paper which was published in the 'United Service Journal,' showing the continuity observable in the various ideas submitted for adoption in the army at that time.

Later, in 1867-8 and 9, I published three papers, which, in order to adapt them to the institution at which they were read, I called 'Lectures on Primitive Warfare,' but which, in reality, were treatises on the development of primitive weapons, in which it was shown how the earliest weapons of savages arose from the selection of natural forms of sticks and stones, and were developed gradually into the forms in which they are now used. I also traced the development of the forms of implements of the bronze age and their transition into those of the iron age. These papers were followed by others on the same subject read at the Royal Institution and elsewhere, relating to the development of special branches, such as Early Modes of Navigation, Forms of Ornament, Primitive Locks and Keys, the Distribution of the Bow, and its development into what I termed the *composite* bow in Asia and America, and other subjects.

Meanwhile I had formed a museum in which the objects to which the papers related were arranged in developmental order. This was exhibited by the Science and Art Department at Bethnal Green from 1874 to 1878, and at South Kensington from that date to 1885; and a catalogue *raisonné* was published by the Department, which went through two editions. After that, wishing to find a permanent home for it, where it would increase and multiply, I presented it to the University of Oxford, the University having granted 10,000*l.* to build a museum to contain it. It is there known as the 'Pitt-Rivers Collection,' and is arranged in the same order as at South Kensington. Professor Moseley has devoted much attention to the removal and re-arrangement of it up to the time of his recent, but I trust only temporary illness, which has been so great a loss to the University, and which has been felt by no one connected with it more than by myself; for whilst his great experience as a traveller and anthropologist enabled him to improve and add to it, he has at the same time always shown every disposition to do justice to the original collection. Since Professor Moseley's illness it has been in the charge of Mr. H. Balfour, who I am sure will follow in the steps of his predecessor and former chief, and will do his best to enlarge and improve it. He has already added a new series in relation to the ornamentation of arrow-stems, which has been published by the Anthropological Institute. It appears, however, desirable that the same system should be established in other places, and with that view I have for some time past been collecting the materials for a new museum, which, if I live long enough to complete it, I shall probably plant elsewhere.

Before presenting the collection to Oxford I had offered it to the Government,

in the hope that it might form the nucleus of a large educational museum arranged upon the system of development which I had adopted. A very competent committee was appointed to consider the offer, which recommended that it should be accepted, but the Government declined to do so; one of the reasons assigned being that some of the authorities of the British Museum thought it undesirable that two ethnographical museums should exist in London at the same time; this, however, entirely waives the question of the totally different objects that the two museums (at least that part of them which relates to ethnographical specimens) are intended to serve.

The British Museum, with its enormous treasures of art, is itself only in a molluscous and invertebrate condition of development. For the education of the masses it is of no use whatever. It produces nothing but confusion in the minds of those who wander through its long galleries with but little knowledge of the periods to which the objects contained in them relate. The necessity of storing all that can be obtained, and all that is presented to them in the way of specimens, precludes the possibility of a scientific or an educational arrangement.

By the published returns of the Museum it appears that there has been a gradual falling off in the number of visitors since 1882, when the number was 767,873, to 1887, when it had declined to 501,256. This may be partly owing to the increased claims of bands and switchbacks upon public attention, but it cannot be owing to the removal of the Natural History Museum to South Kensington, as has been suggested, because the space formerly occupied by those collections at Bloomsbury has since been filled with objects of greater general interest, and the galleries have been considerably enlarged.

The Science and Art Department at South Kensington has done much for higher education, but for the education of the masses it is of no more use than the British Museum, for the same reason, that its collections are not arranged in sequence, and its galleries are not properly adapted for such an arrangement. Besides these establishments, annual exhibitions on a prodigious scale have been held in London for many years, at an enormous cost, but at the present time not the slightest trace of these remains, and I am not aware of any permanent good that has resulted from them. If one-tenth of the cost of these temporary exhibitions had been devoted to permanent collections, we should by this time have the finest industrial museum in the world. Throughout the whole series of these annual temporary collections, only one, viz., the American department of the Fisheries Exhibition, was arranged upon scientific principles, and that was arranged upon the plan adopted by the National Museum at Washington. It appears probable from the experience of the present year that these annual exhibitions are on the decline. Large iron buildings have been erected in different places, some of which would meet all the requirements of a permanent museum. The Olympia occupies $3\frac{1}{2}$ acres, the Italian Exhibition as much as 7 acres. There can be little doubt, I think, that the long avenues of potted meats and other articles of commonplace merchandise, which now constitute the chief part of the objects exhibited in these places, must before long cease to be attractive and must be replaced by something else, and in view of such a change I venture to put in a plea for a national anthropological museum upon a large scale, using the term in its broadest sense, arranged stratigraphically in concentric rings upon the plan of the diagram now exhibited. It is a large proposal, no doubt, but one which, considering the number of years I have devoted to the subject, I hope I shall not be thought presumptuous in submitting for the consideration of the Anthropological Section of this Association.

The palæolithic period being the earliest, would occupy the central ring, and having fewer varieties of form would require the smallest space. Next to it the neolithic and bronze age would be arranged in two concentric rings, and would contain, besides the relics of those periods, models of prehistoric monuments, bone caves, and other places interesting on account of the prehistoric finds that have been made in them. After that, in expanding order, would come Egyptian, Greek, Assyrian, and Roman antiquities, to be followed by objects of the Anglo-Saxon, Frankish, and Merovingian periods; these again in developmental outward expansion would be surrounded by mediæval antiquities, and the outer rings of all

might then be devoted to showing the evolution of such modern arts as could be placed in continuity with those of antiquity.

In order that the best objects might be selected to represent the different periods and keep up the succession of forms which would constitute the chief object of the museum, I would confine the exhibition chiefly to casts, reproductions, and models, the latter being, in my opinion, a means of representing primitive arts, which has not yet been sufficiently made use of, but which in my own small local museum at Farnham, Dorsetshire, I have employed to a considerable extent, having as many as twenty-three models, similar to those now exhibited, of places in which things have been found within an area of two miles.

The several sections and rings would be superintended by directors and assistants, whose function it would be to obtain reproductions and models of the objects best adapted to display the continuity of their several arts and periods; and the arts selected for representation should be those in which this continuity could be most persistently adhered to. Amongst these the following might be named:—Pottery, architecture, house furniture, modes of navigation, tools, weapons, weaving apparatus, painting, sculpture, modes of land transport and horse furniture, ornamentation, personal ornament, hunting and fishing apparatus, machinery, fortification, modes of burial, agriculture, ancient monuments, domestication of animals, toys, means of heating and providing light, the use of food, narcotics, and so forth.

Miscellaneous collections calculated to confuse the several series, and having no bearing on development, should be avoided, but physical anthropology relating to man as an animal, might find its place in the several sections.

I have purposely avoided in my brief sketch of this scheme giving unnecessary details. Any cut-and-dried plan would have to be greatly altered, according to the possibilities of the case, when the time for action arrived. My object is to ventilate the general idea of a large anthropological Rotunda, which I have always thought would be the final outcome of the activity which has shown itself in this branch of science during the last few years, and which I have reason to believe is destined to come into being before long. In such an institution the position of each phase of art development shows itself at once by its distance from the centre of the space, and the collateral branches would be arranged to merge into each other according to their geographical positions.

The advantages of such an institution would be appreciated, not by anthropologists and archæologists only. It would adapt itself more especially to the limited time for study at the disposal of the working classes, for whose education it is unnecessary to say that at the present time we are all most deeply concerned. Although it is customary to speak of working men as uneducated, education is a relative term, and it is well to remember that in all that relates to the material arts they have, in the way of technical skill and handicraft, a better groundwork for appreciating what is put before them than the upper classes. That they are able to educate themselves by means of a well-arranged museum, my own experience, even with the imperfect arrangements that have been at my command, enables me to testify. Anything which tends to impress the mind with the slow growth and stability of human institutions and industries, and their dependence upon antiquity, must, I think, contribute to check revolutionary ideas, and the tendency which now exists, and which is encouraged by some who should know better, to break drastically with the past, and must help to inculcate conservative principles, which are urgently needed at the present time, if the civilisation that we enjoy is to be maintained and to be permitted to develop itself.

The next subject to which I would draw your attention is the present working of the Act for the Preservation of Ancient Monuments, with the carrying out of which I have been entrusted during the last five years.

It is unnecessary to speak of the measures that have been taken in other countries which have preceded us in the work of protecting ancient monuments. Their system of land tenure and division of property is different from ours, and the same measures are not equally applicable.

In 1882 a Bill was passed through Parliament known as the Ancient Monuments Act, to enable those who desired to do so, to place the ancient monuments belonging to them, under protection of the Government, and to make it illegal for future owners or others to destroy them : also to enable local magistrates to punish summarily, with a fine of 5*l.* or imprisonment for one month, offences committed under the Act. No power is taken to compel any owner to place his monument under the Act, but provision is made for a small annual expenditure in order to preserve the monuments offered voluntarily by their owners. A schedule of certain monuments was attached to the Act, without the consent of the owners, merely to indicate the monuments to which the Act applied, but these, like any others, had to be voluntarily offered before the Government could accept them. Any other monuments not in the schedule could be accepted, but only after the offer of them had been laid 40 days before Parliament, in order, I presume, that the country might not become charged with the preservation of monuments that were unworthy of protection.

In November 1882, I was asked by Lord Stalbridge, in a complimentary letter, written by desire of the Prime Minister, to undertake the office of Inspector, intimating at the same time that my position as landowner would place me in a favourable position for dealing with other landowners to whom the monuments belonged, and I accepted the post, hoping to render a public service, not, perhaps, sufficiently considering the difficulties that I should have to encounter, and the amount of time that would have to be devoted to it.

A Permissive Act naturally implies that there is some one in the country who desires to make use of it ; whereas, as a fact, no owner has voluntarily offered any monument to be put under the Act, except one to whom I shall refer again presently ; all have had to be sought out and asked to accept the Act, and of the owners of scheduled monuments the larger number have refused.

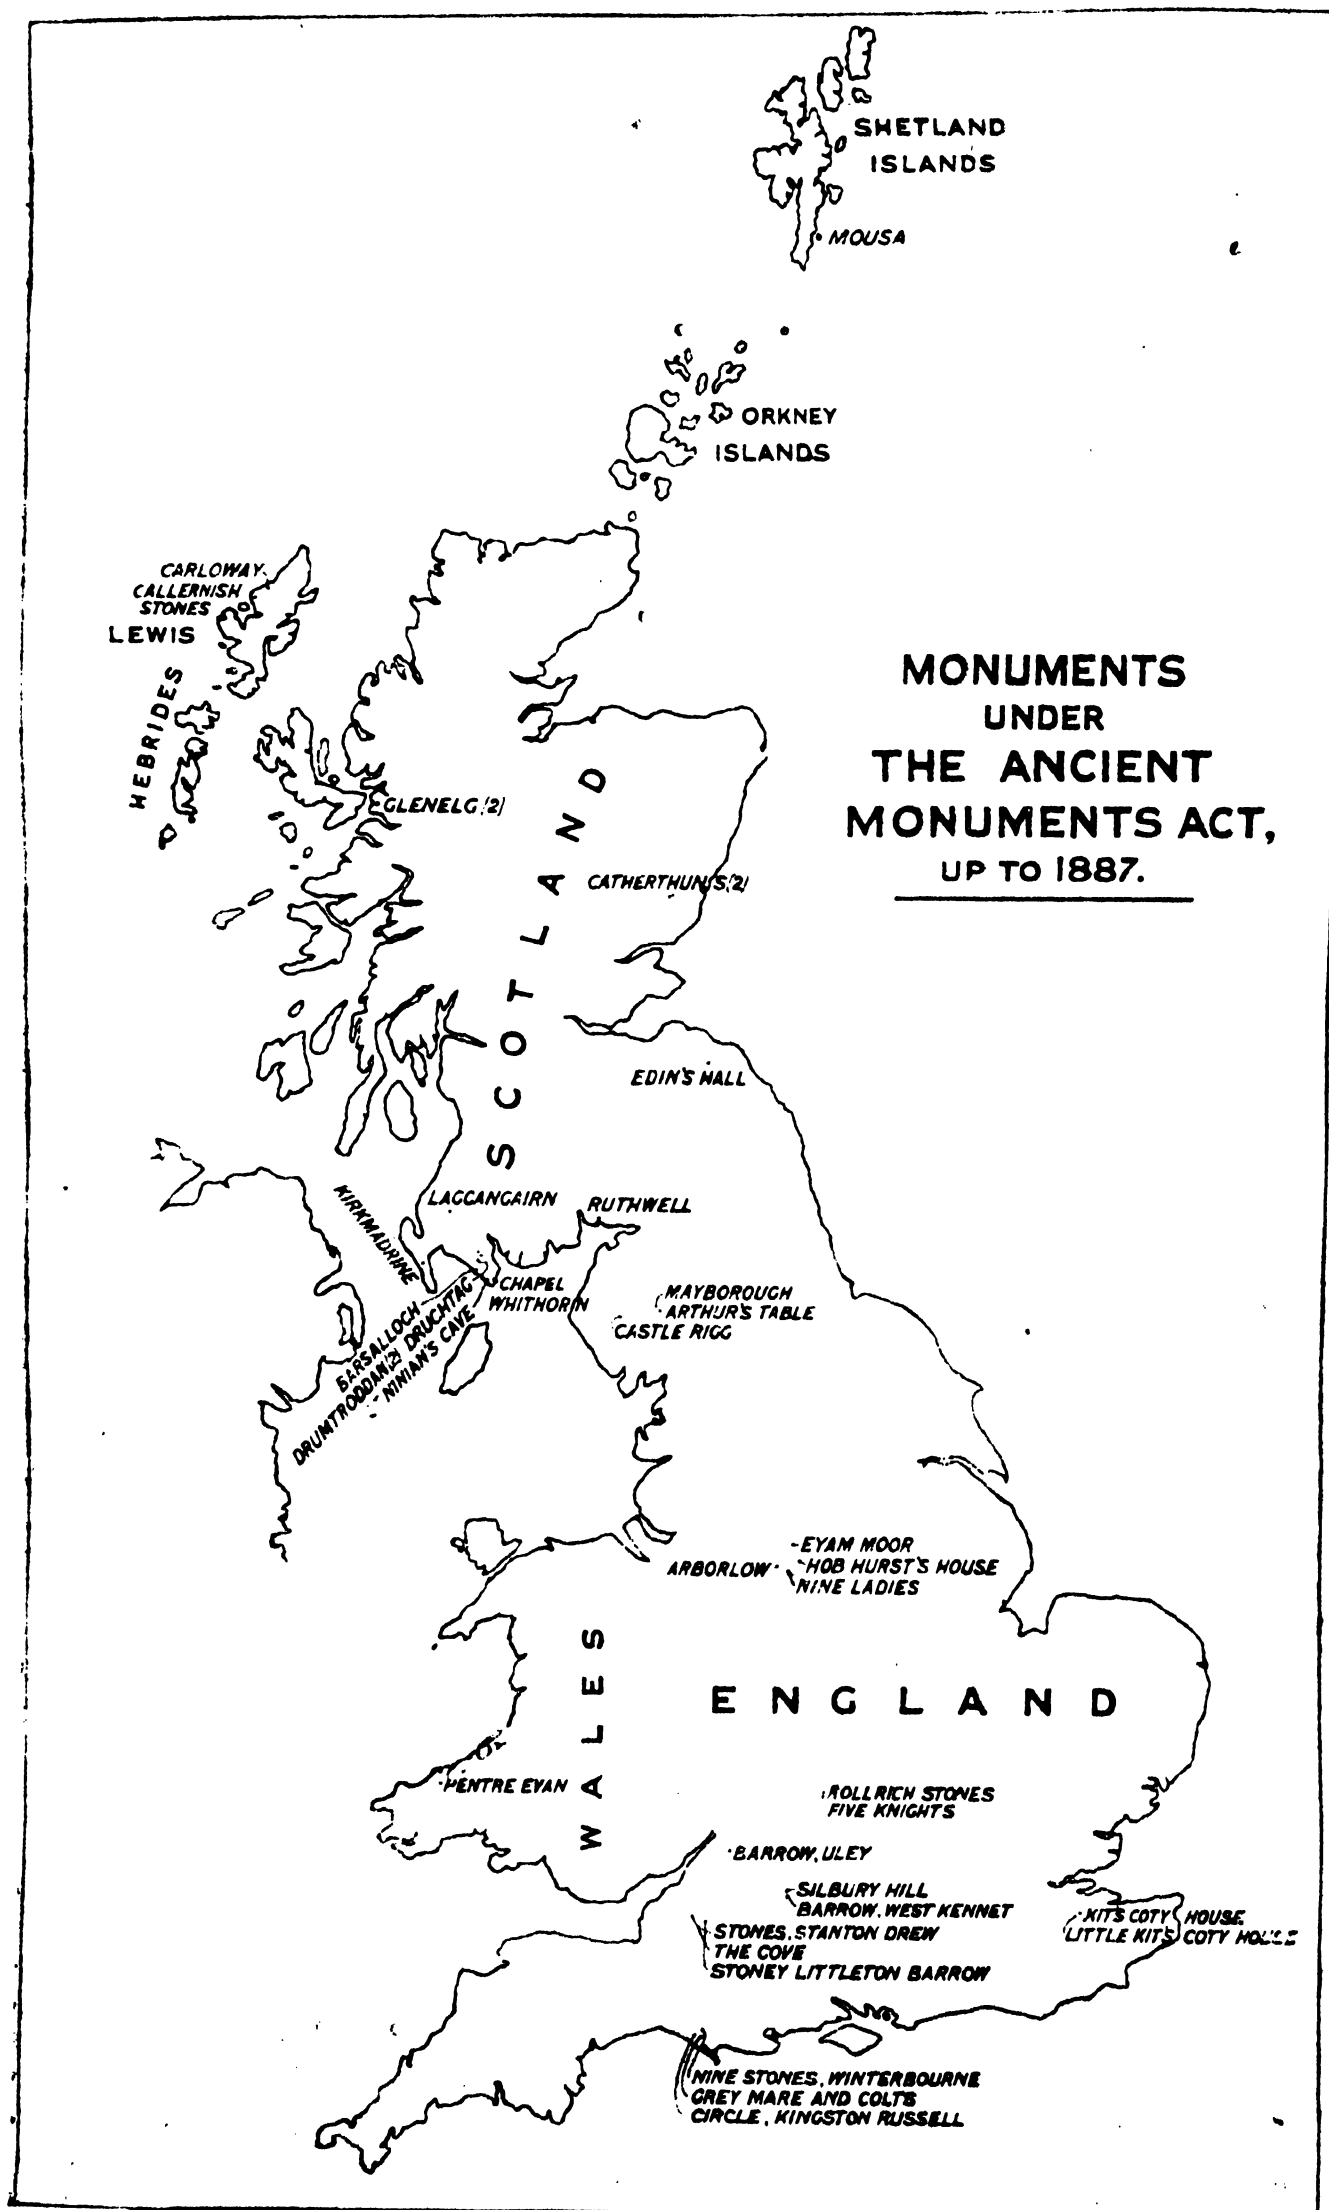

Sir John Lubbock was chiefly instrumental in passing the Bill through Parliament, although in the condition in which it actually passed it was not his Bill. He had proposed to make the Act compulsory in the case of some of the more important monuments, but the proposal had been overruled on the ground of its being an improper interference with private ownership.

Being a member of the Liberty and Property Defence League, I have lately received a list of 55 measures which have been brought before Parliament in the session of 1888, which that body have thought it desirable to oppose on account of their interference with private property, nearly every one of which would have dealt more hardly with the owners of property than the Ancient Monuments Act would have done had it been made compulsory. But all these measures have been proposed by members of Parliament with the view of catching the votes of particular constituencies, whereas the ancient monuments have no votes to give and very few people to vote for them. Sir John Lubbock had included his own monuments in the original schedule, but finding that the Act in its final form was purely permissive, and not believing, as he told me at the time, that anyone would voluntarily make use of it, naturally being unwilling to put his own property at a disadvantage, by being the only one to come under it, he at first hesitated to sign the deed for their inclusion in the Act, though he did so readily after the adhesion of other owners assured him that he would not stand quite alone.

Finding myself involved in the matter I have done what I could to work it out, and with some success.

The accompanying map of Great Britain (see next page) shows the monuments that I have been the means of obtaining by the consent of their owners.

The Pictish Tower at Mousa in the Shetlands, which is well known to be the best preserved monument of this class in the country, has been included by the owner, Mr. Bruce, and some necessary repairs have been done to it by the Government. In the Orkneys the owners of the scheduled monuments declined to make use of the Act, but they are well looked after. The same applies to the Bass of Inverurie, the Vitrified Fort on the hill of Noath, the pillar stones at Newton, in the Garioch, and the British settlement at Harefaulds, in Lauderdale, which latter, however, is in such ruinous condition that the remains of it are scarcely worth preserving. The Suenos stone near Forres ; the Cairns at Clava, on the banks of

the Nairn; the Cat-stane at Kirkliston; the Burgh of Clickanim, have also been withheld by their owners, but most of them are very well taken care of. The Cairns at Minnigaff were nearly destroyed before they were scheduled, and are not worth preserving. The inscribed stone in St. Vigean's churchyard is preserved in the porch of the church, but it is not included. On the other hand Edin's Hall, the largest and most southern of the remains of the Pictish Towers in Berwickshire, has been included by Mr. J. S. Fraser-Tytler; the Black and White Catherthuns have been added by Miss Carnegie Arbuthnot; both these are large camps having ramparts of stones and earthworks round them, and they are described in General Roy's work. The Pictish Towers at Glenelg have been included by Mr. James Bruce Bailey; they are in a very bad state of repair, and have been propped up by the Government. The inscribed stones at Laggangairn, New Luce, have been included by Lord Stair; they are at a great distance from any road or habitation, and the protection afforded them, beyond the powers contained in the Act, must be regarded as nominal. The Peter's stone, on the road from Wigton to Whithorn, has not been added; it is an important stone, and is in a dangerous position, it has already suffered damage, and it is to be hoped it will be included hereafter. The chapel on the Isle of Whithorn, supposed to be that built by St. Ninian, has been included by Mr. R. Johnstone Stewart; this was not in the schedule. The Pillars of Kirkmadrine have been included by Mrs. Ommaney McTaggart; they are the earliest Christian monuments in the country. I suggested that Government should contribute towards building a small chapel to contain them, which has been done. The Cross at Ruthwell, with its remarkable runes, which were gradually being destroyed and covered with lichen so that its inscription could not be read, has also been added. I suggested that the Government should contribute towards building an annex to the neighbouring church to contain it, which has been done. This was not in the schedule. The cup-marked rock of Drumtrodden, Wigtonshire, has been added by Sir Herbert Maxwell, and Government has granted a certain sum towards building a shed over it to preserve it. It was not in the schedule, but is a good example of its class. Barsalloch Fort, Wigtonshire, the Moat Hill of Druchtag, the Drumtrodden standing stones, Wigtonshire, have also been added by Sir Herbert Maxwell. St. Ninian's Cave, with its early Christian crosses, has been included by Mr. Johnstone Stewart. In the island of Lewis the remarkable standing stones in the form of a cross at Callernish, and the Broch at Carloway, have been added by Lady Matheson. This latter is, next to Mousa, the best Pictish tower in the country. In Cumberland the Stone Circle on Castle Rigg has been put under the Act by Miss Edmondson. In Westmoreland Arthur's Round Table, an earthen circle with a ditch in the interior, and Mayborough, a large circle with an embankment of stones and the remains of a stone circle within, have been included by Lord Brougham. In Derbyshire, Arborlow, a large circle similar to Arthur's Round Table, with the remains of a stone circle, the stones of which are prostrate, and a large tumulus near it, have been added by the Duke of Rutland. Hob Hurst's House, and the Circle on Eyam Moor, which also has a large cairn close to it, have been included by the Duke of Devonshire, and the Nine Ladies, a circle of small stones on Stanton Moor, by Major Thornhill. In Gloucestershire, Uleybury, a long barrow with a well-preserved stone chamber, has been added by Colonel Kingscote. In Oxfordshire the Rollrich stones have been included by Mr. J. Reade. In Kent, Kit's Coty House by Mr. Brassey, which is the remains of a long barrow, the traces of which can be seen, with part of the stone chamber remaining. In Somerset the stone circles at Stanton Drew by Mr. S. B. Coates, and the Cove there by Mr. Fowler; the chambered tumulus at Stoney Littleton by Lord Hylton. In Wiltshire, the long barrow at West Kennet by the Rev. R. M. Ashe, and Silbury Hill by Sir John Lubbock. In Dorsetshire the chambered long barrow, called the Grey Mare and Colts, near Gorwell, by Mr. A. B. Sheridan; the circle of Nine Stones near Bridehead Park by Mr. R. Williams; the stone circle on Kingston Russell Farm by the Duke of Bedford, and in Wales the Pentre Evan cromlech, one of the largest in the country, by Lord Kensington—making in all thirty-six which have been placed under the Act with the consent of their owners. All these and many

others have been surveyed ; plans, drawings, and sections have been made of them, which are contained in the book now upon the table, which is open for the inspection of the members. I hope to publish these shortly. Besides these monuments which are included under the Act, a good deal of useful work has been done by communicating with the owners of other monuments, without using the Act.

I think it speaks well for the landowners that so many should have been willing to accept the Act, considering that few of them take much interest in antiquities. There is not a more public-spirited body in the world than the much-abused landowners of England.

Those who have refused have generally done so on the grounds that they wish to remain responsible for their own monuments, and I think I may say, from my own observations, that there is very little damage to prehistoric monuments going on at the present time. Public opinion has done more than any Act of Parliament could do, and it appears to me that it is generally known throughout the country that any wilful damage to the monuments would be universally condemned.

But it is well to consider the operation of the Act, and how it may be improved. The provision which makes it illegal, ever after, to destroy the monuments that are now placed under the Act by their owners, and to enable magistrates to punish offenders summarily, appears to me excellent and worthy to be retained. But there are defects to which it would be well to give attention. By the present Act the Government are made responsible for all the monuments that are included, which entails expense, and as members of Parliament generally take very little interest in ancient monuments, and the great object of Government must always be to curtail expenditure, additions to the list are not as a rule encouraged.

I last year obtained eleven new monuments, but I was told that this was too many and that some must be omitted, so I selected three of the least important and they have not been included. This, I think, is objectionable, the two provisions of the Act which I have mentioned should be applied as widely as possible. If the provision making Government responsible for the preservation of the whole of them is altered, there will be no inducement on the part of the authorities to reduce the number to be included. At present local archæologists wash their hands of the matter, thinking that there is a Government Inspector whose business it is to look after the monuments. This is a mistake ; the proper function of the Inspector is simply to look after the monuments that are included, and to advise the Commissioners—Not to obtain new monuments for the Act. I have done so because I was charged in a special manner with the organisation and working of the Act on its first introduction, but it is beyond the proper functions of the Inspector. I have done it as a private individual who takes an interest in the subject, and any other private individual may do the same. Moreover, it is impossible for an Inspector to stand sentry over all the monuments that are put under the Act. The police are requested to look after them as well as they can, but damage must occasionally be done which local archæologists are in a better position to ascertain and to remedy, using the provisions of the Act for the purpose.

It may be that my position as a landowner, as Lord Stalbridge said in his letter asking me to take the appointment, may have had some effect in enabling me to persuade some of the other landowners, but you cannot ensure always having a landowner for an Inspector, and it is desirable now to put the Act on a working footing. It is much to be wished that local archæological societies should be made to feel themselves responsible both for the inclusion of monuments under the Act and their preservation afterwards ; the Act arms them with full powers for the purpose if they think proper to use it.

At present no archæological society has rendered any assistance whatever, but Sir Herbert Maxwell, in Galloway, has not only offered his own monuments, he has persuaded his neighbours to do the same. What Sir Herbert Maxwell can do others equally public-spirited can do also, if it is clearly understood that it rests with them to take action in the matter, and I think it should rest with them, because, being local, they can do more than a single Inspector charged with the supervision of the whole of the monuments of Great Britain. I think that the

Government should continue to appropriate a small sum (it is now under 200*l.* a year) to apply to such purposes as may be thought desirable, such as building sheds to preserve the monuments, but that they should not necessarily be held responsible for all the monuments placed under the Act, and that the Bill being a permissive one, it should rest with the public to make use of it or not, as they may think proper. If there is no demand for the preservation of monuments, there is no reason why the country should be saddled with the expense of it. If there is a demand, let those who are interested use the law on the subject as they use any other to prosecute delinquents. I think also, the provision that the new monuments before being included should rest forty days before Parliament, might be advantageously abolished. The First Commissioner, with the practical knowledge of the Inspector, is fully competent to decide upon the monuments to be included. It is evident that if it were desired to save any monument that might be threatened, the forty days would afford ample time to enable the destruction to be carried out before the Act could be applied. With these alterations I think the Act would take root in the country and produce better results. Of one thing, however, I feel certain, that as long as the owner of a monument takes an interest in it he is the best person that the public can look to for the preservation of it.

In conclusion it may perhaps interest the meeting if I say a few words upon the results of my recent excavations on the borders of Dorset and Wilts, upon which I have been at work for the last eight years, the detailed account of which is recorded in the two quarto volumes extending to 541 pages and 159 plates, the last of which is just completed.

I have excavated numerous barrows of the bronze age near Rushmore, about half-way between Salisbury and Blandford. Winkelsbury Camp has been examined and sections cut through the ramparts; an Anglo-Saxon cemetery near it has been dug out, and two Romano-British villages thoroughly explored, the positions of which are shown on the map now exhibited on the walls, a reduced facsimile of which is given on page 835.

In recording these excavations I have acted on the principle that views upon anthropological subjects are constantly on the change, as our imperfect knowledge of the early inhabitants of the country increases, and that when the records of excavations are confined to opinions and results, it is probable that those facts only which coincide with the theories current at the time, receive the prominence they deserve.

The requirements of the future demand that everything should be recorded and tabulated in such a way as to be of easy access hereafter. I have therefore established a system of relic tables in which, without confusing the text and making it unreadable, every object, however small and apparently trivial, is inserted, and the great majority of them are figured in the plates.

It would occupy too much time to enter into details on the present occasion. The result has been to show by a computation from the bones of twenty-eight individuals, found buried in pits in the villages, that the Romanised Britons of this district were an exceedingly small race, having an average stature of not more than 5 feet 2·6 inches for the males, and 4 feet 10·9 inches for the females; that the tallest man was only 5 feet 7·8 inches, and he was an inch and a half taller than the next tallest man.

In head form, the great majority of twenty-six skeletons measured were mesaticephalic and mostly coffin-shaped, but three were hyper-dolichocephalic and two brachycephalic, which shows that the head form approached that of the neolithic, long barrow people, with a probable admixture of either Roman or bronze age types.

The stature is slightly less than that given by Thurnam for the long barrow people of this district, but Dr. Garson informs me that, in a paper which he will read at this meeting, he will show that the height of the Romano-Britons whom I have discovered tallies as nearly as possible with that of some long barrow bones found near Devizes. All are of course shorter than the skeletons of the bronze age, two of which I have found in the same locality, and which are of the usual tall stature and round-headed types of that people.

The Romano-Britons are also considerably shorter than the skeletons of the Anglo-Saxons found in the cemetery at Winkelbury, which are described in my second volume.

The problem, therefore, with respect to these Romanised Britons, appears to be this:—are they the descendants of the long barrow people, and do they owe their small stature to that circumstance, or is their small size to be attributed to their largest men having been drafted away into the Roman legions abroad?

Professor Rolleston examined a number of skeletons from a cemetery at Frilford, which he believed to be Romanised Britons, and found that they were of large size, but in my address to the Royal Archæological Institute at Salisbury, last year, I expressed some doubt about the period of these skeletons, and in a paper since published by Dr. Beddoe, I see that he rejects the evidence of their being Romano-Britons upon the same ground that I had doubted it, and he quotes Barnard Davies and Thurnam for the occurrence of other skeletons of these people of the same or nearly the same stature as those of the villages that I have explored.

We are therefore evidently beginning to accumulate reliable information about these people, whose physical peculiarities are less known to us than any other prehistoric, or rather non-historic, race, that has contributed to the population of this country.

Thurnam showed that the large-sized, round-headed Belgæ probably penetrated no further westward than the borders of the district I am speaking of, and that the bowl barrows and the long barrows of the Stone Age predominated to the westward of it.

Since the present volume of my excavations was in print, I have quite recently made another discovery of considerable interest bearing upon this question.

Bokerley Dyke is an ancient entrenchment which cuts across the Old Roman road from Old Sarum to Badbury Rings. It is an earthwork of considerable magnitude, with a ditch on the north-east side of it. It appears to have originally occupied all the open downland spaces intervening between the ancient woods, which latter probably, by means of felled trees, afforded sufficient defence without earthworks. It extends with its dependencies and detached prolongations more or less all the way from White Sheet Hill on the north-west to Blagdon Hill on the south-east, a distance of about nine miles. Its origin and use have been frequently discussed by archæologists, but no one has hitherto assigned a right date to it. I have now cut two broad sections through it on either side of the Roman road, models of which are exhibited, with the result of proving that it is late Roman, or post-Roman, and is of the same date as the villages, Roman coins to the amount of 500, of late date, extending to Constantinus and Gratianus, and pottery, having been found in both sections, all through the rampart, down to the old surface line. It appears that the dyke had been cut through ground occupied at an earlier date by the Romanised Britons, and that in forming the ditch they threw up the refuse from the habitations to form the bank, including the scattered coins and pottery. A human skeleton of similar character to those found in the villages was also discovered beneath the old surface line in one of the sections, the old surface line being clearly marked over it, showing that it had been buried there before the rampart was thrown over it. From this it appears probable that this dyke was thrown up to defend the Romano-British villages that are situated to the westward or rear of it, from an attack from the east, and that this must in all probability have been done at the time when the Saxon invaders were pressing upon them from the eastward.

This discovery throws a flood of light upon the history of this part of the country at that time, and shows that the Britons must have made a stout defence against their Anglo-Saxon conquerors, sufficient perhaps to account for the apparent predominance of British blood which has been noticed amongst the existing population of the district.

Wansdyke, which runs from a spot not far to the north of the Bokerley Dyke in the direction of Bath, has the same defensive attitude as Bokerley, and the exami-

nation of it, which it is proposed to make, will show whether or not it is of the same period.

The observations of Dr. Beddoe and other physical anthropologists upon the present population of the country show that the people of the South-West of England are, as a rule, shorter and darker than those to the eastward, and my own observations upon the people of this particular district will, when they are systematised, tend to define the area of this ethnical frontier more precisely. It would be a remarkable result if it should hereafter be shown that the physical changes observable in the distribution of the existing population are in any way coincident with these lines of defensive earthworks of the Roman or post-Roman age: and if it should be further shown that the same physical characteristics have persistently belonged to the people of this region ever since the time of the neolithic folk of the long barrows, we shall find ourselves in the presence of anthropological deductions of some value in their bearing on the history of England. I purposely avoid speaking with confidence upon this point, feeling certain that the necessary evidence for deciding the question lies buried in the soil of the district, and will hereafter be unearthed. I shall resume the inquiry as soon as the harvest, if such it can be called this year, is over, but without bias, and with a mind prepared to throw over any preconceived hypothesis, the moment it shows itself to be untenable.

MAP SHEWING THE AREA FORMERLY OCCUPIED BY CRANBORNE CHASE,
WITH THE ANTIQUITIES CONTAINED IN IT.

The following Reports and Papers were read:—

1. *Report of the Committee for investigating the effects of different occupations and employments on the Physical Development of the Human Body.*—See Reports, p. 100.

-
2. *Second Report of the Committee for ascertaining and recording the localities in the British Islands in which evidences of the existence of Prehistoric Inhabitants of the country are found.*—See Reports, p. 289.
-

3. *The Constitutional Characteristics of those who dwell in large Towns, as relating to Degeneracy of Race.* By G. B. BARRON, M.D., L.R.C.S.E., M.R.C.S., Hon. Surgeon-Major.

The conditions of life and their general surroundings largely influence and materially affect the physical and constitutional characteristics of town dwellers.

The 'vital force,' or 'energy,' of the town dweller is inferior to the 'vital force' of the country man. This is to be found in the general unfitness and incapability of the town dweller to undergo continued violent exertion and the long endurance of fatigue. The various factors at work night and day upon the constitution of the poorer class dwelling in towns develop that form of disease known as tuberculosis and pulmonary consumption. The town man is constitutionally dwarfed, and his life is, man for man, *weaker, shorter, and more uncertain* than that of the country man; and the general tendency of his ailments is of the asthenic type.

I hold the opinion that the deterioration is more in physique, loss of muscular power, attenuation of muscular fibre, loss of integrity of cell structure, and consequent liability to the invasion of disease, *rather than in actual stature of inch measurement*. The true causes are 'bad air' and 'bad habits' of life. My contention is, that it is in the loss of physical tonicity, vital capacity, and vital force, that the degeneracy is found, and not in actual loss of stature. Included in the phrase 'bad air,' I mean bad sanitation and over-crowding.

For thirty years I have been working at this question, and the more I examine it the more I am convinced of the accuracy of my conclusions. Sailors, fishermen, agricultural labourers, and sportsmen are rarely the victims of consumption. The chief cause of consumption is foul air. Air filled with some kinds of dust and other noxious ingredients, produces a form of phthisis, as is seen in the Sheffield knife-grinders, &c. Where people are huddled together in insanitary dwellings, such as are found in the crowded courts and alleys of large towns, they are specially prone to this disease. Experiments made by Dr. Brown-Séquard on animals prove this. The value of fresh air in preventing disease was known to Hippocrates, Celsus, Aretæus, and Pliny. The fishermen of the Hebrides and Labrador are specially exempt.

The absence of pure air produces pallor and feebleness of constitutional vigour; the tissues of the human body lose their tonicity and contractile power; the pent-up denizens of courts and alleys in our large towns must necessarily degenerate in physical competency; and their offspring is of feeble type; lowered vitality and impoverished physique is the result.

These observations deal only with those who habitually dwell in towns.

The second factor is 'bad habits of life,' including the non-observance of rules of health, and intemperance, with the various forms of 'impurity.' These tell a sad story by smiting, with devitalising severity, the offspring to the third and fourth generations, as well as the direct victims who indulge in them.

Imperfect feeding, and consequent malnutrition, causes degeneracy to be emphasised. The digestive capacity of the town dweller is not so perfect as that of

the countryman, and he is more liable to suffer from the products of imperfect assimilation. The result often shows itself in the form of the uric acid diathesis and the evils due to that condition, Bright's disease, and allied diseases. The pernicious habit of too much indulgence in tea-drinking is injurious.

It is not the male sex alone we have to consider in this question. The mothers of this part of future England produce an enfeebled offspring, and their development is bad, and they are impaired in physique.

Town children are more quick-witted and artful, and adroit in cunning acquisitiveness; but that does not imply superior intellectual development. It is supposed that rapid growth of the nervous system retards the bodily development. I do not think so.

No satisfactory answer has been supplied to the paramount question, 'Is the town dweller degenerating in stature of inch measurement?' The constant immigration into the towns of country men and women, introducing fresh blood into the old stock by marriage, and thus renovating it, renders the solution of the problem difficult. This is a decided counterpoise to degeneracy. The statistics of the Anthropometric Society rather point to a lowered stature, but they are not conclusive unless they can be applied to pure town dwellers of two or three generations' duration. Mr. Francis Galton measured 9,000 persons, and appears to have established the fact that Cambridge students are rather taller and heavier than the mean population.

As regards the physical impairment or degeneracy of the population of towns in stature, the report of the Anthropometric Committee at the Southport meeting says 'few statistics are in existence which help to throw light on this subject.' The measurements of height and weight of the Factory Commission of 1833, and the report to the Local Government Board of the employment of young persons in factories in 1873, show that there is no appreciable lowering of stature.

The 'Lancet' Commission on the Sweating System discloses a terrible state of things. The daily occupations of town dwellers and their homes and workshops are very insanitary, and must lead to an impoverished condition of the animal economy.

The remedies are Imperial legislation to improve the social conditions of the town dwellers. Insanitary surroundings, over-crowding, uncleanness, impurity, intemperance, must all be swept away. The children must be educated in the pure air of the country. Make the parents sober and moral; give them pure air and plenty of it, and away fly pale faces, dyspepsia, crooked backs (generally resulting from tuberculosis), lowered vitality, stunted development, muscular attenuation, and the imperfect elimination of functional products.

The purely physical side of human nature demands our attention. The instinctive rush of the poorer classes into towns in quest of the means to live has greatly helped to complicate the problem of relief. Hardships of various kinds tend to accentuate their wretchedness, and they seek solace too often in the unhealthy pursuit of unrighteous habits. The problem of poverty has to be reckoned with if the English race in large towns is to retain a fair standard of physical integrity.

4. *The Physique of the Swiss as influenced by Race and by Media.*

By Dr. BEDDOE, F.R.S., V.P.A.I.

The paper was founded on the official recruiting returns. The average stature of Swiss recruits (including the rejected) between the ages of nineteen and twenty is 163.5 cms., or 64.3 inches; the full-grown stature perhaps nearly an inch higher. It is greater, generally speaking, in the districts where French or Romansch is spoken than where the language is Italian or German. From the point of view of race it is highest in the Helveto-Burgundian area, i.e. the Jura, contiguous to the French department of the Doubs, where the stature is the highest in France, lowest in the Kelto-Alemannic area, especially around Appenzell, and in the Ober-

land. Weaving and embroidery, which are the chief occupations about Appenzell, St. Gall, &c., may be blamed as productive of degeneration, but watchmaking, in the Jura, does not seem to be so; and the low position of the Oberland, which extends to other points besides stature, is difficult to explain. Goitre seems to have a geological distribution; myopia belongs to the towns, to the highly-educated, to the Germans (readers of German type), to the lacemakers and embroiderers. On the whole, the physical development is healthiest in Nidwalden and Tessin, and it is suggested by the Swiss officials that the diet in these two cantons consists largely of cheese.

5. *On Colour-blindness.* By KARL GROSSMANN, M.D.

The question of colour-blindness, which, when first described 90 years ago, had only the interest of a scientific curiozum, has become one of very great importance in our age of ocean- and railroad-racing.

Still, although everyone, with the exception perhaps of the official authorities, will be of the same opinion as to the danger of employing colour-blind people in posts where coloured signals are to be distinguished, not the same unity exists as to the theories concerning colour-blindness and colour-perception. The old theory of Thomas Young (1802) obtained a new lease by the support of no less a name than Helmholtz; but this theory is fast losing ground against the theory of Hering, who admits two pairs of simple or fundamental colours. A third theory, that of the evolution of the colour-sense, has, as one of its supporters, Mr. W. E. Gladstone. But it has not been considered anything else than a misunderstood Darwinistic deduction, carried out with a great amount of philological knowledge.

Colour-blindness in its typical form is congenital, and, with the very rarest exception, is double-sided: it is either red-green-blindness or blue-yellow-blindness, or total colour-blindness. As red-green-blindness is the usual and most important form, we will consider it exclusively here for simplicity's sake.

The colour-blind individual 'makes mistakes' in distinguishing certain colours. To him the ripe strawberry and its leaves, the blossom of the pomegranate-tree and its foliage, the blush on a rosy cheek and the sky, are three pairs of equal colours. The names given to certain colours by the sufferer may be right or wrong; they do not convey to them the correct notions. A keen perception of dark and light shades exists and often leads to the correct naming of colours. Still, naming is utterly misleading as a rule. Holmgren has therefore modified Seebeck's mode of testing by placing a bundle of coloured skeins before the colour-blind, who has to select to a given shade all those which match. If there be two different colours which appear absolutely alike to the colour-blind, a pattern made of these two colours will appear as of one colour only. On this principle Stilling based his plates, an excellent idea, which, however, fails very often; the reasons will be seen soon.

The author calls two such apparently identical but different fundamental colours 'twin-colours.' Such colours are, for instance, a certain yellow and green. To these two we may find a third fundamental colour, equally identical to the colour-blind, a certain red, thus forming with the two others a set of 'triplet-colours.' He now found that while a certain green and yellow were twin-colours for all his colour-blind patients, the corresponding red was right for some, too dark for others, too light for others again. This he found was due to the way in which the different eyes perceived the spectrum. If the red end of the spectrum was shortened, certain reds appeared darker than to eyes with a normal extension of the spectrum. Dr. Grossmann utilised this by embroidering letters of three colours so as to form on a brownish ground a red letter, say an F, completing it by green in such a manner as to form a B. A red-green-blind eye with normal spectrum will then see a blank ground; while one with a shortened spectrum sees the letter F dark on a lighter ground.

Another difficulty is the variability of the daylight, which affects the different colours in twin combinations to a different degree. Both these reasons explain why Stilling's plates so often fail.

The wool letters, though very nice, handy, and without gloss, are very apt to fade.

In order to get a more uniform light, and also to more readily imitate the signal-lights, patterns were formed of twin-coloured glass, cut into small squares and arranged into mosaic figures, between two plain glasses so as to form a slide which is put into a lantern. These slides are not subject to the variability of daylight, and will never fade. The little squares are hardly destructible.

FRIDAY, SEPTEMBER 7.

The following Papers were read :—

1. *On Human Bones discovered by General Pitt-Rivers at Woodcuts, Rotherley, &c. By Dr. BEDDOE, F.R.S.*

The paper contained a comparison of the Romano-British skulls found at Woodcuts and Rotherley, and of the Anglo-Saxon ones at Winklebury, with remarks on the striking difference in stature between the two former and the latter series. The differences in size (of the skulls) were inconsiderable, and the average cephalic index was about the same in the Romano-Britons and the Saxons, falling just below 75. The elliptic form predominated in the Saxons, the ovoid and coffin-shaped in the Britons. The frontal radius and arc of Busk were larger in the Saxons. In the Britons neolithic forms, pure or mixed, were frequently observed. Dental caries was more frequent in the Britons. The author doubted whether the stature of the Britons was quite so dwarfish as had been supposed; if allowances were made for the soft parts, for the advanced age of some of the individuals, or if they were supposed to have the shortness of limb often found in people of low stature, the male average might even be raised as high as somewhere between 5 ft. 4 in. and 5 feet 5 in. (164 centimetres). In any case, however, the stature was very low, whether compared with that of the Winklebury Saxons (over 5 feet 7), or with the bronze people, or with Davis and Thurnam's long-barrow men. The author inclined to agree with the suggestion of General Pitt-Rivers that the race might have degenerated in stature under the combined influence of oppression, poverty, &c., and of the abstraction, generation after generation, of the taller men for service in the legions.

-
2. *Human Remains from Wiltshire.*
By J. G. GARSON, M.D., V.P. Anth. Inst.

In his important work on 'Excavations in Cranborne Chase, near Rushmore' General Pitt-Rivers has asked the following question regarding the human skeletons he found: 'What race can these people be taken to represent? Are they the survivors of the neolithic population which after being driven westward by successive races of Celts and others continued to exist in the out-of-the-way parts of this region up to Roman times, for which hypothesis the crouched position of the interments and their markedly dolichocephalic or hyperdolichocephalic skulls appear to afford some justification, or are they simply the remnants of a larger race of Britons deteriorated by slavery and reduced in stature by the drafting of their largest men into the Roman legions abroad? In order to throw some light on this important subject, the author has examined several skeletons obtained in various parts of Wiltshire from excavations of barrows containing human remains associated with neolithic implements. Of these neolithic people there seem to have been two varieties; both of these are characterised by having long narrow skulls, but the skull of the one variety differed from that of the other in that, while one is of regularly oval outline, the other has flattened sides which give it a coffin- or pear-shaped appearance. The skulls examined by the author showed

both those varieties to exist in Wiltshire, eight being of the oval form and four of the coffin-shaped variety. General Pitt-Rivers' specimens showed the same varieties to exist, but the oval form to be greatly predominant in numbers. The author found two specimens to be hyperdolichocephalic (Cephalic Index, 65-69), seven dolichocephalic (Index, 70-74), three mesaticephalic (Index, 75-79), and no brachycephalic specimens. Of the specimens excavated by General Pitt-Rivers, three are hyperdolichocephalic, eleven dolichocephalic, ten mesaticephalic, and two brachycephalic. The characters presented by the neolithic skulls showed evidence of the people at that time not being of absolutely pure race. Examination of General Pitt-Rivers' specimens showed that the characters of the skull were identical with those of the early race, though there was evidence that in the interval of time which separated the two sets of interments the people had become, as was to be expected, somewhat more mixed. This fact would account for the greater number of mesaticephalic persons among the skeletons excavated by General Pitt-Rivers, both the Celts and the Romans with whom they came in contact having much rounder heads than themselves, while the brachycephalic skulls found by General Pitt-Rivers proved themselves to be those of Celts or Romans who had been interred with the Britons. Passing to an examination of the long bones of the skeleton, the author found the average stature of the neolithic persons he had examined, estimated from the length of the femur and humerus is, 1,588 mm. (5 ft. 2.5 inches); others, estimated from the radius (consequently not to be so much depended on), averaged 5 ft. 5 inches, the average of the whole being 1,628 mm. (= 5 feet 4 inches), which is the identical average of the skeletons from Woodcuts village. If the statures estimated from the radius be excluded—which, owing to their being much greater than those estimated from other bones, may fairly be done—the average stature of the neolithic Briton and of all the Romano-British people found by General Pitt-Rivers at both villages is exactly the same.

From the characters of the skull and the statures being as nearly as possible identical with those of the early dolichocephalic and neolithic inhabitants of Britain, the author concludes that the human remains obtained from General Pitt-Rivers' excavations are no other than those of the neolithic people who had existed down to Roman times in a comparative state of purity. The evidence of this being the case seemed to him to be corroborated by the fact that down to the present day it is easy to trace remnants of the old Iberian race in various parts of England and Wales, notwithstanding the great interchange of population which has taken place during the present century.

3. *On a Method of investigating the Development of Institutions; applied to Laws of Marriage and Descent.* By EDWARD B. TYLOR, F.R.S.

With the view of applying direct numerical method to anthropology, the writer has compiled schedules of the systems of marriage and descent among some 350 peoples of the world, so as to ascertain by means of a 'method of adhesions' how far each rule co-exists or not with other rules, and what have been the directions of development from one rule to another. As a first test of the results to be obtained by this means, the barbaric custom is examined which forbids the husband and his wife's parents (though on a friendly footing) to speak or look at one another, or mention one another's names. Some seventy peoples practise this or the converse custom of the wife and her husband's relatives being obliged ceremonially to 'cut' one another. On classifying the marriage rules of mankind, a marked distinction is found to lie between those peoples whose custom is for the husband to reside with his wife's family and those where he removes her to his own home. It appears that the avoidance custom between the husband and the wife's family belongs preponderantly (in fourteen cases, as compared with eight computed as likely to happen by chance) to the group of cases where the husband goes to live with the wife's family. This implies a causal connection between the customs of avoidance and residence, suggesting as a reason that the husband, being an interloper in the wife's family, must be treated as a stranger; to use an English idiom expressing the situation, he is not 'recognised.' Other varieties of the custom show similar preponderant

adhesions. Another custom, here called *teknonymy*, or naming the parent from the child, prevails among more than thirty peoples; as an example was mentioned the name of Ra-mary, or Father of Mary, by which Moffat was generally known in Africa. This custom proves on examination to adhere closely to those of residence and avoidance, the three occurring together among eleven peoples, that is, more than six times as often as might be expected to happen by chance concurrence. Their connection finds satisfactory explanation in the accounts given of the Cree Indians of Canada, where the husband lives in his wife's house, but never speaks to his parents-in-law till his first child is born; this alters the whole situation, for though the father is not a member of the family, his child is, and so confers on him the status of 'Father of So-and-so,' which becomes his name, the whole being then brought to a logical conclusion by the family ceasing to cut him. These etiquettes of avoidance furnish an indication of the direction of change in social habit among mankind; there are eight peoples (for instance, the Zulus) where residence is in the husband's family, with the accompanying avoidances, but at the same time avoidance is kept up between the husband and the wife's family, indicating that at a recent period he may have habitually lived with them.

The method of tracing connection between customs is next applied, with the aid of diagrams, to the two great divisions of human society, the matriarchal and the patriarchal, or as the present writer prefers to call them, maternal and paternal systems. In the maternal system descent and inheritance follow the mother's side, and the guardian of the children is the maternal uncle, not the father, whose assertion of parental rights belongs to the paternal system with descent and inheritance on his side. The problem to be solved is, which of the two systems is the more primitive, and to this the present method gives calculable answers, showing that the drift of society has been from the maternal to the paternal system. Thus the law by which the eldest son of an African chief inherits his stepmothers as wives belongs only to the stage where patriarchy is in force, which is consistent with this being the later system; had it been the earlier system the custom would have survived into the midst of matriarchy, where, in fact, it is not found. The custom of the 'couvade,' where at the birth of the child the father is nursed and dieted and otherwise behaves as though he were the mother, is evidence in the same direction. In the maternal stage of society, where the father has hardly any power or position, this farcical proceeding is unknown, but where the paternal relation begins to be more developed, we find it asserted among twenty peoples by the ceremony of couvade, which even lasts on, in eight cases, into the full paternal system, being only just extinct in Europe, where it lingered till the end of last century in the Pyrenees. These several customs are so stratified as to demonstrate that Bachofen, McLennan, Bastian, Morgan, Lubbock, Giraud-Teulon, Wilken, Fison, Howitt, Lippert, Post, have judged rightly, from the evidence before them, in taking the matriarchal system as the earlier, from which the patriarchal gradually arose.

The paper continues with the argument that a chief underlying cause of both systems is still traceable in society. A diagram showing the classification of peoples according to residence showed 65 peoples where the husband attaches himself permanently to the wife's family, 76 where such temporary residence is followed by removal to a paternal home, and 151 where the paternal home is resorted to from the first. The changes brought about by the man's ceasing to be in the hands of his wife's kinsmen, and becoming lord of a household of his own, represent, in fact, the transformation of maternal into paternal society. Among the Pueblo Indians the Hon. J. W. Powell, of the Bureau of Ethnology at Washington, has had the opportunity of watching this change brought about by the necessity of removal of families, for agricultural purposes, from the parent settlement.

By the method of adhesions, examination is next made of the practice of wife-capture, recorded among about 100 peoples, as a hostile act, a recognised and condoned mode of marriage, or a mere formality. The two latter kinds (connubial and formal) only come into existence with the paternal system. It is obvious that this must be so, as the capture of a wife, even in pretence, necessarily involves her passing into the husband's home and authority. The system of exogamy or 'marrying-out,' in which husband and wife must belong to different clans, classes,

or families, does not appear to be derived from the practice of capture, as some 14 peoples, representing so early a stage of the maternal system as to have residence in the wife's family, a state of things which could not have followed from capture, nevertheless already forbid marriage within the clan. With reference to the Rev. Lorimer Fison's argument that the Classificatory System of Relationships described in North America, Hindostan, &c., by the Hon. L. H. Morgan, results directly from exogamy in its Australian form, it is here further shown by a table of adhesions that the closest connection exists between exogamy and this system of relationships; and also with the rule of 'cross-cousin marriage' which in several tribes allows marriage between the children of a brother and sister, but not of two brothers or two sisters. By taking these together, it is found that the list of exogamous peoples of the world may be enlarged to over 100. It appears from the testimony of a number of writers that the rule of exogamy, whatever its precise origin, has from the first been a means of binding together tribes and nations by intermarriages between the clans or groups of which they are composed, and thus resisting the disintegrating effects of quarrels, which would separate in permanent hostility the small isolated communities which endogamy tends to form. A community which marries in has no allies outside; these can only be gained by intermarriage, and savage tribes must again and again have had to face the plain alternative, whether they would marry out or be killed out.

It is evident from the tables that the rules of human conduct are amenable to classification, so as to show by strict numerical treatment their relations to one another. It is only at this point that speculative explanation must begin, guided and limited in its course by lines of fact. In the words of Prof. Bastian, the future of anthropology lies in statistical investigation. The present paper shows that the institutions of man are as distinctly stratified as the earth on which he lives, succeeding one another independently of difference of race and language, by similar human nature acting through necessarily changing conditions of savage, barbaric, and civilised life.

4. *Australian Message-sticks and Messengers.* By A. W. HOWITT, F.G.S.

The use of message-sticks is not universal in Australian tribes, and the degree of perfection reached in conveying information by them differs much. Some tribes, such as the Diëri, do not use the message-stick at all, but make use of emblematical tokens, such as the net carried by the Pinya, an armed party detailed by the Council of Headmen of the tribe to execute its sentences upon offenders. Other tribes, such as the Kurnai, use pieces of wood without any markings. Others, again, especially in Eastern Queensland, use message-sticks extensively, which are often elaborately marked, highly ornamented, and even brightly painted. No messenger, who was known to be such, was ever injured.

The message-stick was made by the sender, and was kept by the recipient of the message as a reminder of what he had to do.

For friendly meetings the messenger of the Kurnai, of Gippsland, carried a man's kilt and a woman's apron hung on a reed; but for meetings to settle quarrels or grievances by a set fight, or for hostile purposes generally, the kilt was hung upon the point of a spear.

Among the Wotjoballuk of the Wimmera River in Victoria, the principal man among them prepares a message-stick by making certain notches upon it with a knife. The man who is to be charged with the message looks on, and thus learns the connection between the marks upon the stick and his message. A notch is made at one end to indicate the sender, and probably notches also for those who join him in sending the message. If all the people of a tribe are invited to attend a meeting, the stick is notched from end to end; if part only are invited, then a portion only of the stick is notched; and if very few people are invited to meet or referred to in the verbal message, then a notch is made for each individual as he is named to the messenger.

The messenger carries the stick in a net-bag, and on arriving at the camp to which he was sent, he hands it to the headman at some place apart from the

others, saying to him, 'So-and-so sends you this,' and he then gives his message, referring, as he does so, to the marks on the message-stick.

The author gives an explanation of the method adopted for indicating numbers, which fully disposes of the idea that the paucity of numerals in the languages of the Australian tribes arises from any inability to conceive of more numbers than two, three, or four.

A messenger of death painted his face with pipe-clay when he set out, but did not in this tribe carry any emblematical token.

Among the Wirajuri of New South Wales, when the message was one calling the people together for initiation ceremonies, the messenger carried a 'bull-roarer,' a man's belt, a man's kilt, a bead string, and a white head-band, in addition to the message-stick.

In New South Wales, the Kaiabara tribe use message-sticks cut in the form of a boomerang, to one end of which a shell is tied.

As a rule the notches on a message-stick are only reminders to the messenger of the message he is instructed to deliver, and are unintelligible to a man to whom they have not been explained; but certain notches appear to have a definite meaning and to indicate different classes; and among the Adjadura there is an approach to a fixed rule, according to which these sticks are marked, so that they would convey a certain amount of meaning definitely to an Adjadura headman independently of any verbal message.

5. *Social Regulations in Melanesia.*

By the Rev. R. H. CODRINGTON, D.D.

INTRODUCTORY.—The part of Melanesia in view comprises the Northern New Hebrides, the Banks' Islands, Sta. Cruz, and the South-eastern Solomon Islands. The Social Regulations which obtain among the people are described from personal observation, and from information given by natives. A considerable portion of the whole subject is thus in view, and with particular differences there is a general agreement, from which a wider likeness throughout the Melanesian population may be inferred.

The Social Regulations dealt with are only those relating (I.) to *Marriage*, and (II.) to *Property*.

I. SOCIAL REGULATIONS RELATING TO MARRIAGE.

1. The entire arrangement of society depends on the division of the whole people, in every settlement, large or small, into two or more classes, which are exogamous, and in which descent follows the mother. This division comes first of all things in native thought, and all social arrangements are founded upon it. Mankind, to a woman, was divided into husbands and brothers; womankind, to a man, into wives and sisters—at least, on about the same level of descent. Illustration from a story.

2. The members of these divisions are all intermixed in habitation, property, subordination to a chief, and in the well-understood relationship through the father; the divisions, therefore, are not tribes.

3. Examples from two regions—(a) where these divisions are two, as in the Banks' Islands and Northern New Hebrides; (b) where there are more than two, as in Florida, in the Solomon Islands.

(a) 1. Where there are two divisions there is no name to either. In Mota there are two *veve* (distinction); in Lepers' Island two *wai-vung* (bunch of fruit).

2. The divisions are strictly exogamous; irregular intercourse between members of the same is a heinous crime; avoidance of the person and name of father-in-law, &c., is the custom.

3. No communal marriage in practice, or tradition of it; yet a latent consciousness of the meaning of the words used for husband and wife, mother, &c. The story of Qat shows individual marriage. The levirate, and practice of giving a wife to set up a nephew in the world.

4. Descent through the mother makes the close relation of sister's son and mother's brother; the son takes his mother's place in the family pedigree. Certain rights of the sister's son with his uncle. The mother is in no sense head of the family. The bridegroom takes his bride into his father's house, if not into his own.

5. A certain practice of couvade prevails.

6. No capture in marriage. Adoption of no importance.

(b) 1. In Florida, in the Solomon Islands, and the neighbourhood, is found an example of four or six divisions, called *kema*. In strict exogamy, descent following the mother, and local and political intermixture, all is the same as in the Banks' Islands. But each *kema* has its name, and each has its *buto*, that which the members of it must abstain from. The names are some local, some taken from living creatures. The *buto* is mostly something that must not be eaten.

2. Question whether totems are present. The bird which giving its name to one *kema* is not the *buto* of it, can be eaten. Comparison from the Island of Ulawa.

3. Exceptional condition of part of Malanta and San Cristoval, in the apparent absence of exogamous divisions of the people, and in descent being counted through the father.

II. PROPERTY AND SUCCESSION.

A. 1. Land is everywhere divided into (1) the Town; (2) the Gardens; (3) the Bush. Of these, the two first are held in property, the third is unappropriated.

2. Land is not held in common—i.e., each individual knows his own; yet it is rather possession and use for the time of what belongs to the family, and not to the individual. A chief has no more property in the land than any other man. Sale of land was very rare before Europeans came; and sale of land by a chief beyond his own piece, no true sale. Example at Saa of the fixed native right of property in land. Abundance makes land of little value.

3. Land reclaimed from the bush by an individual, and the site of a town founded on the garden ground of an individual, has a character of its own.

4. Fruit trees planted by one man on another's land, remain the property of the planter and his heirs. In a true sale the accurate and particular knowledge of property in land and trees is remarkably shown.

5. Personal property is in money, pigs, canoes, ornaments, &c.

B. 1. The regular succession to property is that by which it passes to the sister's son, or to others who are of kin through the mother.

2. But that which a man has acquired for himself he may leave to his sons, or his sons and their heirs may claim. This is the source of many quarrels, the character of a piece of land being forgotten, or disputed by the father's kin.

3. Hence a tendency to succession to the father's property by his sons follows the assertion of paternity, and the occupation of new ground.

4. A man's kin still hold a claim on his personal property, but his sons, who are not his kin, will generally obtain it.

6. *On the Funeral Rites and Ceremonies of the Nicobar Islanders.*

By E. H. MAN.

The author, who during a residence of many years in the Nicobar Islands has made a careful study of the habits and customs of the aboriginal inhabitants as well as of their language, forwards a paper treating in detail of the Nicobarese funeral rites and ceremonies.

The mortuary customs in the central and southern islands differ in many points from those observed by the communities inhabiting the northern portions of the Archipelago: all alike appear to indulge in demonstrations of grief, which amount to almost frenzied extravagance, and which are induced in the majority of mourners less by real sorrow than by the dread entertained of, and desire of conciliating the

disembodied spirit, which is credited with peculiar activity and malevolence immediately after its release.

It is incumbent on all relatives and friends to repair as speedily as possible to the hut where a death has taken place, and those who fail to bring with them the customary offering of white or coloured calico must make a valid excuse to the chief mourner, who would otherwise regard the omission as an insult to be remembered and rendered in kind at the earliest opportunity: these offerings vary in quantity from a few yards to an entire piece, and are, as soon as they are presented, torn into lengths of about two yards and utilised for shrouding the corpse; they must be of new material, and may be of red, blue, white, striped, or checked, but never of *black*, calico.

In most of their funeral appointments the Nicobarese have, it appears, an unexplained preference for uneven numbers; the body must be washed *once, thrice, or five* times; it is laid on a bed or pad of the calico offerings, 30 being used for a headman, and 29 or any less uneven number for persons of minor importance; under the pad are placed 3, 5, or 7 Areca spathes, and these again are kept in position by 5, 7, or 9 swathes or bands of calico: curious-shaped pegs to the number of 7 or 9 are also used to secure the body in the grave in order to prevent its abstraction by a class of evil spirits whose energies are supposed to be directed to this end.

A practice analogous to that of harring the ghost by fire, prevails also in these islands, and a pyre is ignited with firesticks—which are only used on these occasions—at the foot of the hut where the dead is lying for the twofold purpose of keeping the disembodied spirit at a distance and apprising friends approaching or passing in a canoe of the sad occurrence.

Mourners are required to abstain from food from the time of the death until after the prescribed cleansing of the dwelling and personal ablutions and lustration by the *menlūana* or priest-medicine-man on the following day; quids of betel and sips of almost boiling water are the only refreshment permitted during the interval: a set period of abstinence is further observed which varies in duration from one to three or even four years.

There are cemeteries attached to every village, in which each family owns a certain area. The natives of the coast and inland tribes in the Southern group leave their dead undisturbed, but at Car Nicobar, Chowra, Teressa and Bompoka ossuaries are found where, after successive exhumations and re-interments, the remains are deposited. At Car Nicobar mortuary huts are kept exclusively for the reception of the dead prior to their interment, and certain sacrificial acts are performed which are of interest. Throughout the group the memory of the departed is kept alive and their manes propitiated by frequent feasts which are celebrated in their honour.

7. *Notes on the Shell-Mounds and Ossuaries of the Choptank River, Maryland, U.S.A.* By the Chevalier R. ELMER REYNOLDS.

This paper was accompanied by a series of stone implements and utensils typical of those found during the writer's research in the region named. Specimens of cremated and other osseous remains were also exhibited as a portion of a collection taken from a very interesting communal ossuary in Dorchester County.

Chapter I.—THE BOOK OF LIFE—contains a brief history of the Choptank and Nantëcoke tribes, which were located on the Choptank river. The history of the Choptank tribe was traced from early historic times until the present. Remnants of these people still live in the states of Maryland and Delaware.

Chapter II.—THE SHORES OF TALBAT—locates and describes the present condition of the following shell-mounds on the northern shore of the Choptank.

Oxford, at the mouth of the river; mound covers several acres of ground, with a depth varying from 1 to 3 feet. Shells much decomposed. Implements, hammers, rude axes, arrows, shards of pottery, &c.

Chloras Bay, 2 miles above; mound on shore of bay $\frac{3}{4}$ mile long, and 100 yards wide, 1 to three feet thick; anciently 8 to 14 feet high; shells removed and converted into lime for agricultural purposes. Remains of several ancient pits in which the oysters were steamed with hot stones and water.

Paleo and neo axes and celts, hammer-stones, mullers and pestles, arrows (hunting and war), spears, knives, scrapers, gorgets, fragments of ceremonial weapons, shards of pottery, &c.

Howell's Point, 2 miles above; large mound and shell-field, whose extent could not be determined as the soil was under cultivation. The greatest deposit of shells, 12 to 14 feet. A few rude paleo implements and utensils.

Roadley Manor, 3 miles above; field on eastern shore of Reid's Creek; mound nearly a mile long by 100 or 200 yards wide, greatest depth 3 or 4 feet. Shells decayed. Indian remains ploughed up. Axes of both types, celts, hammers, arrows, spears, knives, and pear-shaped pendant of serpentine and drilled net-sinker.

Bolingbroke Creek, 2 miles east; 15 or 20 acres covered with shells, greatest depth 3 feet. Paleo axes and celts, nuclei, pottery and arrows, spears, knives and scrapers of jasper. Find jasper *in situ* on the shore. Very important archaeological discovery.

Chancellor's Point, 2 miles above; ancient mound 24 feet high. Remains of Indian found buried in the shells. Polished axes, hammers, arrows, spears, knives, pottery, &c.

Goose Point, 2 miles above. Shells 1 to 3 feet deep and cover many acres. Ancient camp on top of mound. Forty years ago the circles where the Indian lodges were pitched could still be traced. Hammers, arrows, pottery, amygdaloid celts fourteen inches in length and superb double-faced polished axes.

'Ingleside.' 2 miles above. Mound short and wide on high shore. Only 1 to 3 feet remaining. Half a million of bushels removed since 1867. Hammers, arrows, pottery and superb double-faced polished axes.

Jamaica Point. 1 mile up the river. Small shell-field in peach orchard. Rude implements. Large mound (remains of) in field beyond. Shells not more than one foot deep. Implements of quartzite and rock crystal.

Outram Manor. 1 mile above. Shell-field in orchard, depth superficial. Many polished axes and arrows, spears, knives, &c., of quartzite, argillite and jasper. Find an abundance of large jasper pebbles on shore. Colour red, yellow, black and variegated. Cleavage excellent.

Bamberg. 2 miles above. 5 to 7 acres covered with shells at a depth varying from 1 to 3 feet. Oblong ungrooved axes, celts, arrows, hammers, pottery and small implements.

Cox's Farm. 1 mile above. A scattering shell-field, polished axes, nuclei, arrows, pottery and flint-chips. The oyster beds cross at this point, and no more mounds are found above. The river now becomes swampy, except at its channel on the opposite shore.

Chapter III.—THE SEPULCHRES OF DORSET.—*The Tomb of the Kings*.—Circular ossuary discovered in Cambridge while building the new jail in 1883. 16 feet in diameter and 7 feet high. Contained the remains of sixteen Indians seated on rocks, facing inward. Probably men of high rank.

Pre-Columbian Necropolis.—At Sandy Hill. Ossuary secondary, communal; remains cremated by eleven fires. Found 16 feet below the surface in the face of a cliff 70 feet high. Over the ossuary was a mound of shells and the remains of an ancient fishing camp. Depth of shells 1 foot.

Ossuary T-shaped, the horizontal bar 15 feet long, 4 feet wide, and 2 feet thick, extending parallel with the river; the upright bar 30 feet long extending rearward into the hill, the other measurements corresponding with transverse portion.

The writer exhumed all of the remains, 300 skeletons.

Crania of much ethnological value, now in possession of the Army Medical Museum.

Among many interesting pathological conditions found are the following:—

1. Cervical vert. of a child of ten years, the spinous process deflected obliquely to the left by traumatic influence.
2. The remains of a pre-natal child.
3. Several segments of the dorsal and lumbar vert. united by extra-osseous deposits. Adult, cause due to old age, disease, or injury.
4. Lower jaw of an adult who died just before being placed in the crematory fire, as shown by the warped condition of the specimen. Coronoid process deflected by heat.
5. Lower third of right femur, showing comminuted fracture, reunion of splintered bones, intraosseous abscesses, suppuration and escape of pus by nearly a dozen circular openings through the bone. Diseased conditions extended for a long time.

SATURDAY, SEPTEMBER 8.

The following Papers and Reports were read:—

1. *Marriage Customs of the New Britain Group.*
By the Rev. BENJAMIN DANKS.

For marriage purposes the people of New Britain are divided into two classes or divisions. No man may marry a woman of his own class. To do so would bring instant destruction upon the woman, and if not immediate death to the man, his life would never be secure; in fact, sexual intercourse between a man and woman of the same class is regarded in the same light as between brother and sister in a Christian community.

As, however, children are of their mother's totem, it is possible for a man to marry his niece, although there is a great repugnance to such unions among the natives.

Preparations for marriage are various. On Duke of York Island, initiation into the secret society which is called Dukduk seems a sufficient preparation (though not absolutely necessary to marriage) for the boys, and there appears to be no needful preparation for the girls.

On New Ireland some girls wear a fringe across their shoulders until they are marriageable. These are the poorer classes. Others are put into cages, in which they remain four or five years without being allowed to go outside the house in which they are confined.

These cages are conical structures about 7 or 8 feet in height, and about 10 or 12 feet in circumference at the bottom and for about 4 feet from the ground, where they taper off to a point at the top. They are made of the broad leaves of the pandanus tree, sewn quite close together so that no light and very little air can enter. On one side is an opening which is closed by a double door of plaited cocoanut tree and pandanus tree leaves. About 3 feet from the ground there is a stage of bamboos which forms the floor. There is only room for the girl to sit or lie down in a crouched position on the bamboo platform, and her feet are never allowed to touch the ground all the time she is confined in the cage. Great marriage-feasts are provided for these girls when they are taken out of the cages.

The author describes some of the customs in connection with the preparation of young men for marriage on the island of New Britain.

Wives are purchased with shell money, and are often married at a very early age. After the price has been decided and paid the girl may be taken away at once to her husband's house, or she may be allowed to remain with her friends for a considerable time.

On Duke of York Island there is generally a marriage-feast of a superior kind when persons of influence are being married. The women of the town and surrounding district prepare a large number of puddings, and many pigs are killed. Many presents are given to the bride in public, which she is expected afterwards to

return privately. A cocoanut is broken over the heads of the pair, and the milk sprinkled upon them. After this there are periodical feasts for a considerable time, the friends of the bride entertaining the friends of the bridegroom and *vice versa*.

When a man marries a second wife after the death of the first, the female relatives of the dead wife gather together and are permitted to do as much damage to his property as they can.

A man may have as many wives as he can purchase, but if he cannot afford to buy one, and his credit is low, he may have to remain single.

2. Totem Clans and Star Worship. By GEORGE ST. CLAIR, F.G.S.

The author defines *totem* as the crest of a clan, and enumerates briefly the features of the institution. The origin of Totemism is confessedly obscure, the latest views are unsatisfactory; the author has gathered evidence in favour of a new view, and asks to be heard.

Beginning with a small community which has its camp to guard, and perhaps its religious tabernacle, let us suppose that the eldest son of every mother is liable to military service. The camp is divided, say into four quarters, and the young men serve in turn for a fourth part of the year. In larger tribes the division may be into twelve, the year being already divided into months. The religion of the tribe is astral, like that of the ancient Chaldeans, and the watchers know what constellation is uppermost in the first month, and which in the second month, and so on. If the first band finds the Bull Constellation in high heaven in the dead of night, during its month, it will reverence the Bull; the young men will return to their tents at the month's end and speak of the Bull; they will remember that when the Bull is in the ascendant again they will have to do duty again; and they will come to be known as the Bulls. For the like reason others become goats and scorpions, or kangaroos and blacksnakes, according to the names of the star groups with different peoples.

The Bulls tattoo themselves with the bull crest, and carry it as a military ensign. The goats, the kangaroos, &c., do the like.

The Bull Constellation, or the Bull's-eye Star Aldebaran, is the special god of the clan, and is to be revered. The bull quadruped becomes the earthly representative of the starry deity, and is not to be used as food.

The members of the Bull clan being now known as the Bulls, or designated by the equivalent expression, 'Sons of the Bull,' the Bull is said to be their father; the father of the clan, their great ancestor.

But no sooner is the original tribe thus divided into twelve clans than the danger of disruption is perceived, and to counteract it, the rule or custom of exogamy is introduced.

The author meets the preliminary objection that barbarous tribes would not be advanced enough to frame a religious system upon an astronomical basis; and then proceeds to adduce evidence in support of every step of the process. He finds, in reviewing the number of clans in a tribe, a preponderance of the number four corresponding to the quarters of the year, and the number twelve corresponding to the months, during which service would be performed by the clans in rotation. He shows it to be a natural arrangement that totem clans should be found localised in nomes or districts. The curious connection between totemism and the transmigration of souls is explained by the Egyptian belief that the soul, after death, goes the way of the sun, and consequently passes through the zodiacal constellations one after another, and becomes identified with each in turn.

This stellar origin of totemism goes far to account for the widespread character of the institution. Measures for self-defence would be adopted instinctively by all tribes. The heavens are spread before all, and the moon everywhere divides the year into months.

If the theory be true, it not only explains things which have appeared mysterious, but it indicates fresh lines of inquiry. These are briefly specified in the paper.

3. *The Survival of Corporal Penance.* By OSBERT H. HOWARTH.

The author exhibited specimens of the 'disciplinas' or scourges, the use of which, by way of public penance, still survives in the village of Fenâes d'Ajuda, a remote community on the north coast of St. Michael's, Azores. It is presumably a practice which has been continued in this place without interruption since the first colonisation of the islands by the Portuguese in the Middle Ages, and is still exercised with such extreme severity as occasionally to result in death. The features of the belief associated with self-flagellation are peculiar to the place, and to some extent inconsistent with the teaching of the Roman Catholic Church in modern times. They therefore constitute another evidence that, whereas the public exhibition of this penance was repeatedly suppressed in Europe, even during early times, it has escaped attention and been perpetuated in this one instance up to the present year, when, in consequence of the attention recently drawn to it, steps have been taken by the local authority to ensure its extinction.

4. *Notes on Chest-types.* By Dr. G. W. HAMBLETON.

The observations of another year have completely confirmed the research laid before the Section at the Manchester meeting. It has been found very easy to obtain the best type of chest in young people. But anthropologists will be surprised to learn that the type of chest can, with care, be changed in the same direction in mature age. This the author has seen in the case of a diseased chest in a gentleman aged 37. Between the ages of 25 and 33 he has frequently obtained similar results. Here then are facts showing the direct power of the surroundings in making types.

5. *Third Report of the Committee for investigating the Prehistoric Race in the Greek Islands.*—See Reports, p. 99.

6. *Fourth Report of the Committee for investigating and publishing reports on the physical characters, languages, and industrial and social condition of the North-Western Tribes of the Dominion of Canada.*—See Reports, p. 233.

MONDAY, SEPTEMBER 10.

The following Papers were read:—

1. *Necklaces in relation to Prehistoric Commerce.*

By Miss A. W. BUCKLAND.

The object of this paper is to trace the geographical distribution of various forms of necklaces and beads, as indicating some sort of commercial intercourse between the races among whom they are found either in present use, or among the relics of the past.

Among the ancient cave-dwellers of Europe, teeth of men and animals, bored for suspension and intermixed with shells and pieces of bone, were used as necklaces, and similar necklaces are still worn by savages in almost all parts of the world; but in the Andaman Islands necklaces are made of pieces of human bone, and of bones of animals, not bored, but bound to cords, and wood is sometimes made to imitate bone. The same singular substitution exists in the Admiralty Islands, where also human bones are used as neck ornaments. Necklaces formed of discs of white, purple, and red shell, cut with much care and labour from large sea-shells, are used by natives all over America and across the various groups of the Pacific to Japan,

China, and India, where they are worn by the Nagas. These shell discs, known in America as Wampum, form the money of the Red Indians, and are also used as money by the Solomon Islanders. Similar shell discs are found in ancient graves, not only in America, but in Europe; whilst in Africa, ostrich egg-shell discs of the same size and threaded in the same manner, with pieces of skin substituted for the dark shell, are made and worn by Bushmen, Niam-Niams, and other wild tribes in the interior. Similar ostrich egg-shell discs are found in ancient Egyptian and Etruscan tombs, showing prehistoric intercourse between Etruria and Egypt, or the interior of Africa.

The pendants accompanying these necklaces are almost always teeth or shells cut in the form of teeth. The beads used for necklaces and found among ancient relics are of various substances, such as bone, serpentine, gold, silver, bronze, tin and glass, and are often made so as to represent several discs or beads joined together. Beads of this kind are found in the Swiss Lake dwellings, in Spain, in Britain, in Hissarlik and Mycenæ, and of a later date in Livonia and Abyssinia.

Beads of amber, which formed such an important article of commerce in prehistoric times, are found among relics of the Stone Age, and have also been discovered in tombs belonging to the Bronze Age, in all parts of Europe, in Egypt and India, several trade routes being known, whereby amber found its way from the Baltic to the Mediterranean. Of glass beads the most remarkable are those known as adder's stones, still used as a charm to cure cattle diseases. Beads of this kind of one particular pattern known as chevron beads have been found in various parts of Europe, in Great Britain, in Egypt, in the Pelew Islands, and also in ancient graves in Canada and Peru. Similar glass beads are dug up in Ashantee and highly valued, forming part of the Royal jewels. Beads of the same shape, and from the markings upon them, probably of the same kind, appear adorning the necks of monarchs on the sculptured slabs brought by Layard from Assyria.

There is also a melon-shaped bead of various materials, very widely distributed, being found in ancient graves in Mexico, as well as in Assyria and all over Europe.

Many peculiar glass beads are found in Ireland, resembling those of Egypt and Greece, although perhaps of native manufacture copied from older types, and it may be fairly said that the history of necklaces is the history of commercial intercourse both in prehistoric and in modern times.

2. *The Definition of a Nation.* By J. PARK HARRISON, M.A.

The frequent misuse of the terms 'Nation' and 'Nationality' at the present day appears to be due to the idea that race and language are involved in the definition. This is not the case, excepting in the primary and archaic sense of the word. Johnson's definition is simply 'a distinct people : a kingdom,' but the best definition is that given in the dictionary of the French Academy, viz.—'The *whole* population born or naturalised in a country, and living under the same Government'—irrespective of race and language.

3. *Sun-myths in Modern Hellas.* By J. THEODORE BENT.

The personification of the Sun amongst the peasants of modern Greece compares well with the legends of classical times; his beauty, power, and strength endow him with regal attributes, and he is supposed at night-time to seek his kingdom and live in a palace where his mother tends upon him. We have also the Sun's wife and the Sun's daughter, and can compare the Macedonian legend of Heliojenni with the Homeric myths of Perse and her children Circe and Aïetes. The Sun, as messenger, may be compared with the words of the dying Ajax.

The connection between Sun worship and that of the Prophet Elias is very marked in modern Greece. Elias looks after rain, and is the Greek St. Swithip. Churches to him are always found on sites of ancient temples to Apollo. The Macedonian ceremony of Perperouna is referred to, and its connection with other

prayers for rain offered up to St. Elias. In a MS. from Lesbos this idea of union between St. Elias and a power over the elements is clearly shown. Taygetus in Laconia shows too the same connection.

There is a connection between Sun worship and St. George; the *kápa* fires are lit on his day, and the connection is noticeable not only in the islands, but in Macedonia, where a curious swing ceremony is performed on St. George's Day, in honour of the Sun's bride having been swung up to heaven on that day. Also, there is a close connection between St. George and St. John, the universal day for lighting fires on the eve of the summer solstice.

4. *The Ancient Inhabitants of the Canary Islands.*

By J. HARRIS STONE, M.A., F.L.S., F.C.S.

The author stated that the name *Guanche*, though generally used for the old inhabitants of all the seven islands of the Canary group, should properly be only applied to the ancient inhabitants of Teneriffe. The ancient inhabitants of these islands were ignorant of the use of metals, and up to 1402, when the conquest first began, had to all practical intents remained apart from the civilisation of that day. They were a branch of the great Berber race, and probably also a tribe of that white dolicho-cephalic race of cromlech builders which at a very early period swept through Europe. Their connection with the ancient Egyptians was noticeable in many traits and customs. The ornamentations in caves and on pottery which the author had come across in his travels in each island of the archipelago were Egyptian in character. The method of embalming the dead, particularly the practice of removing the entrails by a slit made with the *tabona*, and the wrappings of the corpse, was very similar to that employed by the lower class of Egyptian embalmers. Though the ancient inhabitants of all the islands had so much in common, there were so many specific differences in their languages, manners and customs, that the conclusion was almost forced upon the investigator that they must originally have been peopled by more than one tribe of the same race.

The author had examined a large number of skulls in collections in the islands, and found them very European in contour and general appearance. In a large proportion of those in the collections in the islands he had noticed a peculiar indentation in the frontal bone, usually the left, and to his surprise found that of the twenty-six skulls at the Royal College of Surgeons, no less than fifteen possessed this mark, and of these ten on the left frontal bone.

The ancient inhabitants are now quite extinct as a separate race, but the author in his travels had noticed several traits, manners, and customs of the present inhabitants which were clearly, in his opinion, derived from the old race. The food *gofio* and its method of making and eating; the number of cave dwellings and villages; the still prevalent inter-insular jealousy; the size and great physique of the men of the *Purpurariæ*; the confiding, generous, hospitable character of the *Conejeros*; the use of the vaulting pole; the general absence of bigotry and religious intolerance; the preference to this day of the *Gomeros* to carry baggage on the head; the abomination of butchers; the torchlight fishing; the method of laying-out the dead; the wit of the *Palmeros*; the cleverness with which buildings are constructed with stones without mortar; the honesty of the *Canarios*; the unusual beauty of the peasant women, were points alluded to by the author in illustration of his assertion.

The position of women was considered at some length, the author bringing forward many facts to show that they held a far higher position in the social scale than was usual among ancient nations.

5. *Some Account of the Ancient (præ-Roman) Stronghold of Worlebury, near Weston-super-Mare.* By the Rev. HENRY GEORGE TOMKINS.

Worlebury belongs to a small and highly interesting class of so-called 'British' camps, and in some respects is believed to be unique in England. It has been

minutely described and illustrated by Mr. C. W. Dymond, F.S.A., and the author of this paper, in a work privately printed in 1886, entitled 'Worlebury: an Ancient Stronghold in the County of Somerset,' &c., 4to, with plans and plates. The following account will take principal notice of the rarer features.

1. *Situation*.—On the seaward end of a mountain-limestone ridge running east and west above the town of Weston-super-Mare, Somerset, which lies south of the hill. The ridge, precipitous on the north, slopes away to the south, where many British traces—earthworks, interments, &c.—have been found. The whole hill is about three miles long.

2. *Approaches*.—A gradually ascending oblique way on the south side, entering near the east, and highest, end of the works. An ancient ascent of stone steps leads up on the north side of the hill above Kewstoke, a mile east of the external cattle-enclosure of the camp. Thence the approach is level.

3. *Defensive Works*.—Of very unusual construction. The principal ramparts of dry limestone masonry, complex in structure. A wall built with heart of dry rubble; then on each side lower walls in contact with the central one, the section showing steps or terraces; at the thickest part five or six such walls, forming one very massive work of solid stonework, without mortar and without tool-marks.

Subordinate works, and dry ditches.

Suggestion of stockades considered.

Mr. Dymond's inquiry into analogous works in Wales.

4. *Entrances*.—West, south, north-east.

5. *Pits*, their formation and contents. Some analogous examples. Pottery, weapons, and other relics: stores of corn, &c. Skeletons and detached bones. Remains of animals used for food.

6. *Professor Macalister's report on the skulls*.

7. *General results of inquiry*, and inferences as to the works and the relics.

6. *Celtic Earthworks in Hampshire, in reference to the Density of the Celtic Population.* By T. W. SHORE, F.G.S., F.C.S.

The remains of Celtic earthworks in Hampshire, as in some other English counties, are numerous, as many as forty remaining in a state of preservation more or less complete, and others formerly existed. They are of various kinds and shapes, and where they enclose areas and form the so-called camps they are of very different dimensions. Most of them are hill fortresses, but there are also marsh and peninsular fortresses, and one example exists of a small former insular refuge. The present surroundings of these earthworks are of service in assisting to determine their original uses, for although the woodland features may be changed, the variations in hill and dale, and the geological conditions connected with the dry chalk hills, the chalk streams, and the alluvial meadow-land through which they flow, are the same as in Celtic time.

The camps could scarcely have been permanently inhabited sites, for in Hampshire at least few traces of dwellings, or of articles of domestic use, have been found within them, from which and other circumstances it appears that these untrenched areas were strongholds for defence in case of attack. If this is allowed, then these areas must have had a distinct relationship to the number of people required for their defence and to the population, and their capital or head of cattle, they were intended to shelter. No Celtic or other village community or aggregation of such communities would be likely to construct defensive earthworks larger than their powers of defence; otherwise these works would be a source of weakness. If these considerations are allowed, some approximately accurate inferences concerning the relative density, and perhaps concerning the absolute density, of the Celtic population within reach of the shelter of these camps, may be drawn from their positions and the extent of their intrenchment and areas.

The largest Hampshire camps are placed where large open areas must have existed, and the smallest are forest forts at the present day.

The water supply of the hill fortresses would probably be by dew or cloud

ponds, similar to those which exist in or near them at the present time, and are sufficient for the daily supply of water even in summer for large flocks of sheep. Some of these hill camp sites are capped with the Tertiary *débris* known as clay with flints resting on chalk, so that as many dew-ponds as might be necessary could be formed.

Walbury, the largest Hampshire earthwork at the north-west corner of the county, is 550 yards from north to south, and 783 yards from east to west, is covered with some clay with flints, and overlooks the Kennet Valley. The people for whom it was a place of refuge must have lived on the northern as well as on the southern side of it. The naturally great open areas of land near it show that a large population could have lived within reach of it, and its great extent shows that it could have afforded shelter for some thousands of people and cattle. From these circumstances and the implements of the later stone period found in and near it, the author thinks that a relatively large population lived round Walbury in Neolithic time. He thinks this population was considerably larger round Walbury than round St. Catherine's Hill, Winchester, because the earthwork at Walbury is much larger than that on St. Catherine's Hill.

• There are in the valley of the Test and of its branch, the Micheldever stream, five earthworks, situated at nearly the same distances apart, all of them of about the same size, and having near them areas of open downland and alluvial meadow land, not very dissimilar in extent. From these circumstances the author of the paper considers that the populations living within reach of these earthworks were numerically about the same, and much smaller than the population round Walbury, which is so much greater in area and the extent of its intrenchment.

The peninsular earthwork of Bransbury, at the junction of the Test with the Micheldever stream, is one of much interest, defended by the marshes and by a single line of intrenchment from marsh to marsh. The author is of opinion that Bransbury must have served as a stronghold for a population sufficiently numerous at least to have been able to defend the line of the earthwork.

The author has met with no evidence in Hampshire of the Anglo-Saxon extermination of their Celtic predecessors, but, on the contrary, that county contains evidence in support of the opposite view, viz., that a considerable proportion of the Celts was spared and became blended with the West Saxons. Some early village communities living within easy reach of hill fortresses of defence appear to have continued in a modified condition in early Anglo-Saxon time, that at Burghclere being one, a place which has undoubtedly derived its name from two Celtic earthworks on high hills, having remains of communal fields close to them, and much black earth from a former inhabited site in a valley near them. These earthworks are not far from the 'Seven Barrows' of North Hampshire. A valley which is the only natural pass between the hills for many miles lies between them, and Clere was a tall place as late as the time of the Domesday Survey. A relatively large population, sufficient to defend these earthworks, must have lived in the Clere district, a very ancient clearing in forest land.

The author considers the alodial tax known as *Burh-bote* in Anglo-Saxon time to be an intelligible tax when considered in reference to such a place as Burghclere. Many such alodial obligations existed in the Isle of Wight as late as the date of the Domesday Survey, and appear to have had as early an origin as the earliest fortification at Carisbrook, by the common defence of which the land in the Isle of Wight was long afterwards held. As land gradually ceased to be held in community and became held in severalty, the obligations of local defence would remain as an alodial obligation.

The author considers the measure of the Celtic earthworks to be a measure of the Celtic populations, and to indicate approximately the density of such populations around these fortresses.

TUESDAY, SEPTEMBER 11.

The following Papers were read:—

1. *The Monument known as 'King Orry's Grave' compared with Tumuli in Gloucestershire.* By Miss A. W. BUCKLAND.

The monument known as 'King Orry's Grave,' in the Isle of Man, belongs to the Chambered Long Barrows, described by Thurnam, which are found chiefly in Gloucestershire and Wiltshire, and are always regarded as the earliest of our monuments, being assigned by all antiquaries to the neolithic age.

The points common to all these barrows are the long, somewhat ovate shape of the covering mound, the rudely arched principal chamber, and of the passage leading to it, generally pointing east and west, and the square form of the enclosed chambers. All these are found in 'King Orry's Grave,' which has in addition a singular form of entrance to the principal chamber, of which only a few instances are known. This consists of an elliptical opening cut in two large stones, forming an egg-shaped aperture through which it is possible to creep.

Thurnam supposed that this opening was made to facilitate fresh burials from time to time, but, as in the majority of these long-chambered tumuli, the entrance is through an arch formed of three stones, and in all cases the entrance is carefully covered up and concealed, Miss Buckland suggests that in the case of these ovate openings the burials were probably those of priests, and that the elaborately cut opening symbolised the doctrine of the new birth, of which the egg was, and still is, typical, and which was taught alike by Indian Brahmins, Egyptian priests, and the mystical Druids. The only known openings to tumuli similar to that of 'King Orry's Grave' are three in Gloucestershire, at Rodmarton, Avening, and Leighterton, one in Brittany, and two, the Men-an-Tol, in Cornwall, and that at the Museum of St. Germain, Paris; but in the Men-an-Tol the hole is cut in a single stone. 'King Orry's Grave' has one especial feature—that of a tall monolith, ten feet in height, rising from the mound; whilst in plan it appears to resemble the one at Mané Lud, Brittany, and one at West Kennet, Wiltshire. But according to the description of Oswald it had originally a circle at one end and a crescent at the other, suggestive of sun and moon worship.

In many of the Gloucestershire long barrows cleft skulls have been found, and, from the account given of a similar skull having been found with a skeleton and the bones of a dog buried in the ruins of Peel Cathedral, Miss Buckland suggests that this skeleton may have come originally from one of the chambered tumuli in the island, of which two at least are mentioned besides 'King Orry's Grave,' which is the best known. Thurnam assigns the Gloucestershire tumuli to the Dobuni, but it is evident that the same people built these in the Isle of Man, and the question arises whether they came originally from Gloucestershire through Wales, or from Brittany.

2. *Observations made in the Anthropometric Laboratory at Manchester.*
By GEORGE W. BLOXAM, M.A., and J. G. GARSON, M.D.

Two hundred persons had been examined, of whom 102 were men and 98 women. The average age of the men was 41·7 years, while that of the women was 32·1 years.

There was a marked difference in both sexes between the power of the two eyes.

One case only of absolute colour-blindness had been observed, the subject being a Jew.

The average height of the men was rather more than 68 inches, that of the women about four inches less. The weight averaged 150 lbs. for the men, and some 25 lbs. less for the women.

There was an enormous difference between the chest capacity of the men and that of the women, which could only be accounted for by the female practice of wearing corsets.

3. *On the Early Races of Western Asia.* By Major C. R. CONDER, R.E.

The students of Aryan and Semitic antiquity have found themselves confronted for the last forty years in Western Asia, in Greece, and Italy, by languages and racial types neither Aryan nor Semitic, and showing races whose civilisation is earlier. In three cases these languages are found to be Turanian (in the more limited meaning of the word), viz. Akkadian, Medic, and Etruscan. As regards these languages the study of Akkadian, as it existed about 3000 B.C., shows a grammar nearest to that of Turkic languages and even of the Manchu Tartars, and a vocabulary which has been in great measure recovered, though in part still doubtful, and which, while comparable with Finnic and Ugrian languages, is yet nearest to the Turkic. The language of the Medes known from the inscriptions of Darius, about 500 B.C., has a similar but more advanced grammar, and a vocabulary held by Oppert and others to be nearest the Turkic. The Etruscan, of which the numerals were shown by Dr. Isaac Taylor in 1874 to be Turanian, is also found to compare in grammar and vocabulary with the Akkadian.

The question now raised is whether the early population of Asia Minor and Syria, of which traces are recoverable from various sources, did not belong to the same stock. In Asia Minor, Lenormant believed a Turanian stock to have existed very early, and in Syria this was the belief of the late Dr. Birch, and has been urged by Captain Conder from 1883 onwards.

(1) *As regards Syria.*—The names of towns and persons are recoverable from Egyptian monuments and papyri in 1600 and 1340 B.C. In the south these are mainly Semitic. In the north the country of the Phœnicians and Kheta gives us 200 town names and 20 royal names which are neither Semitic nor Aryan. Comparing these words with Akkadian, and with the living Turkic and Ugrian languages, the author finds that the translation is suitable. Among the personal words, *Tar*, *Sar*, *Lul*, *Nazi*, *Essebu* and *Tarkun* are the most distinctive, and among geographical terms *Tami*, 'building,' *Su*, 'river,' *Tep*, 'hill,' and others are distinctive of the Turkic dialects. From these words it is fairly safe to conclude that a Turanian population inhabited Syria in the earliest historic times akin to the Turks and Turkomans still found in the same region.

In Northern Syria also certain hieroglyphic inscriptions of a very archaic kind are found, which, by general consent of archaeologists, have been attributed to the same race; and, by the same general consent, the hieratic character derived from these hieroglyphics is recognisable in the later syllabary generally known as Cypriote or Asianic. This connection was first discovered by Professor Sayce. The author has proposed to treat these syllables as representing Turkic words, and by this means to recover the sounds of the original hieroglyphics of Northern Syria. He finds that by this method it is possible to read the short bi-lingual known as the 'Boss of Tarkondemos.' The words *Ma* and *Ku*, for 'country' and 'king,' which he thus recovered in 1887, though questioned by Dr. Sayce as not being Akkadian, are admitted by other authorities to belong to that language and are widely-spread Turanian words.

The evidence of physiognomy, dress, and religious customs among the Kheta, or Hittites, points to the same conclusion. Their type of face is recognised to be Tartaric or Mongolian, and their adoration of the sun, moon, mountains, clouds, rivers, and the sea is similar to the beliefs of other Turanian peoples, as is their practice of exogamy mentioned in the Bible.

The author further points out that the Kara Khitai, or 'black Khitans,' of Eastern Turkestan—an important people in Central Asia as early as the time of the geographer Ptolemy—possessed a name identical with that of the Kheta. Their language is similar in many words to Akkadian, their religious beliefs and warlike customs resembled those of the Kheta. The pigtailed found to be worn by the latter are also of Tartar origin in China.

(2) *Asia Minor*.—The early 'barbarian' population of Asia Minor is stated by the ancients to have been akin to the Etruscan race. In various parts of Asia Minor hieroglyphics like those of the Hittites are found, and cylinders used as amulets, not unlike the Akkadian cylinders, occur in this region, which have similar hieroglyphic emblems. The syllabary above mentioned as Asianic also exists in these regions, and in the island of Lemnos a text recently discovered proves to be written in a language and character closely similar to the Etruscan. A few words of the Lydian and Carian languages have also come down to us, and among these the author has recognised important Turkic words, such, for instance, as the Carian *Taba* for a 'rock,' and the Lydian *Lailas*, 'tyrant.' The ancient nomenclature of Asia Minor seems to indicate the same connection, as do also the Carian personal names. As an instance, the river Sangarius may be compared with the river Sangari in Manchuria, being one out of many coincidences.

The only alternative to the supposition that a Turkic population once spread over Mesopotamia, Syria, and Asia Minor, is the supposition that these tribes, or some of them, belonged to the Lesghic group in the Caucasus, to which Lenormant proposed to refer the ancient Vannic population. The reason why the author has not accepted this supposition is that the study of this group of languages, though long since proposed, has not led to any satisfactory result, or enabled any student to interpret the sounds of the various languages of Syria and Asia Minor above noticed, or those of the Syrian hieroglyphics, in the manner in which they can be interpreted through the use of the Tartar or Ugrian languages.

The author appends a list of 100 Hittite words recovered from the monuments and compared with Turanian words, and other short lists of Carian, Lydian, Phrygian, and Scythian words of the same class.

4. *Discoveries in Asia Minor.* By J. THEODORE BENT.

During a cruise along the south coast of Asia Minor the author found the sites of three ancient towns and identified them by inscriptions. One in Caria, near a curious little harbour, which apparently was called Kasarea in antiquity, is alluded to by Ptolemy and Pliny as *Κρήσσα λιμὴν*. Near the mouth of the gulf of Makri, the ancient Telmessus, we found in a hollow basin, surrounded by mountains, the ruins of a town called Lydæ, also incidentally mentioned by Ptolemy, but hitherto undiscovered. Here amongst other remains we found 33 inscriptions, many of them of great local interest, introducing us to a doctor, Aristobulus by name, mentioned by Galen, and to numerous consuls and pro-consuls of Rome who ruled here, and whose names appear in 'Waddington's *Fastes Asiatiques*.' Local offices and dignitaries, family names and customs are referred to on all these inscriptions. About five miles from Lydæ, inland, we came across other ruins—a fortress buried in a thick forest overlooking a lake; and from inscriptions we identified this place as Lissa, but it does not occur in the lists of Lycian towns given by any ancient or modern geographer. At various other known sites we found inscriptions which have not been published.

5. *Notes on the Hyksôs, or Shepherd-Kings of Egypt.* By the Rev. HENRY GEORGE TOMKINS.

Some accounts of the sources of information on this subject. Chaldæa compared with lower Egypt. Two great streams of migration. Maspero's view of the conquest of Egypt. Forerunners of the Hyksôs. The hordes distinguished from their rulers. Mariette's opinion.

A sketch of the inferences to be derived from:—

(A.) Proper names of the Hyksôs; (B.) Characteristics of their statuary; (C.) Their religion.

- A. 1. Salatis (or Saïtes), compared with Set-Shalit as read on a statue.
2. Bnôn. 3. Pachnan. 4. Apophis, on sphinxes of Sân and else-

where. Apepi Râ-âa-us, and Apepi Râ-âa-qenen (or -ab-taui). 5. Iannas; Râ-ian or Khian of the Bubastis fragment. His throne-name found on the lion of Baghdad. 6. Staän, Set-an, or An-set, Inferences:

- B. Statuary ascribed to the Hyksôs. Sphinxes of Sâh. Statue from the Fyûm. Ludovisi head. Statuette of the Louvre. Head of Apepi, and throne and legs of Râ-ian or Khian at Bubastis. Characteristics and probable affinity of these works.
- C. Sketch of ascertained points with regard to Set or Sutekh, the god of the Hyksôs and Kheta, and the religious war which ended in the expulsion of the Shepherd-Kings.

Sketch of the struggle between the Theban kings and the Hyksôs; the death of Râ-skenen-ta-âa-qen in battle; the conclusive victory of Aahmes and pursuit of the enemy into Palestine; campaigns of successive Pharaohs of the great eighteenth dynasty, and monumental evidences of Egyptian conquest in Mesopotamia and the Overlordship of Babylonia, including some account of the lately-discovered cuneiform tablets of Tel-el-Amarna.

The retrospective value of these historical and geographical materials in regard to the Hyksôs, their rulers, and what became of them.

The probable relation of these things to the narratives of the Old Testament.

6. *Pelasgians, Etruscans, and Iberians; their relations to the Founders of the Chaldean and Egyptian Civilisations.* By J. S. STUART GLENNIE, M.A.

In the author's paper on 'The Archaian (non-Semitic and non-Aryan) White Races, and their part in the History of Civilisation,' read at the last Manchester Meeting of the British Association, an attempt was made to show that the first civilisations of Chaldea and of Egypt were founded by the action on Dark Races of White Races, neither Aryan nor Semitic; and that the combined results of a great variety of recent researches show that such White Races are an important, and hitherto quite inadequately recognised, element in the ethnology of Asia and of Polynesia, of Africa, of Europe, and of America. It was affirmed, but only very partially proved, that not only in Chaldea and in Egypt, but throughout the world, the civilisations of Semites and of Aryans have been founded on civilisations initiated by some one of these non-Aryan and non-Semitic, or Archaian, White Races. And it is proposed in this paper more fully to prove this proposition with respect to European civilisation, or, in other words, to point out the relations of the pre-Aryan Pelasgians, Etruscans, and Iberians, to the non-Semitic and non-Aryan Stock of White Races to which the founders of the Chaldean and Egyptian civilisations belonged.

It is assumed that we have now sufficient grounds for definitively identifying the Pelasgians and Etruscans with the Pelesta (or Pulista) and Tuirsha of the Egyptian monuments of 1300 B.C., and perhaps also with the Hanebu, or peoples of the North, of 2500 B.C. And the attempt is made to show that, if the Pelesta and Tuirsha, and the peoples either directly or indirectly associated with them, cannot be directly connected with the founders of either the Chaldean or the Egyptian civilisation, yet they belonged, like the initiators of these civilisations, to the non-Semitic and non-Aryan stock of White Races, and the Pelesta, perhaps, even to the Chaldean branch of that stock; and that the appearance of these Northern peoples in the Mediterranean may be connected with that upbreak of the Old Chaldean Empire, and that beginning of the predominance of the Semites of which the first evidence is found in the Kingship of Sargon I. 3800 B.C. The facts are likewise stated which appear to connect the Iberians of Western Europe, from Spain to Scotland, both with the Libyans, or non-Semitic and non-Aryan White Races of Northern Africa, and with the similar White Races of the Caucasus through the evidences of their former settlements in Asia Minor, and otherwise.

The great aim of this, and of connected papers, is, by proof of ethnological relations, to confirm and extend those results of later research which connect

European origins with the civilisations of Western Asia. Hence, the facts having been pointed out that appear to establish the above-indicated ethnological conclusions, some illustrations will be given of the light that may be thrown on the mythologies, traditions, and folk-lore, not only of Greece and of Rome, but also of Western Europe, by thus connecting the Pelasgians, Etruscans, and Iberians with that stock of non-Semitic and non-Aryan White Races to which belonged the founders of the Chaldean and Egyptian civilisations. Hitherto resemblances of the gods, institutions, &c., of different peoples have been ordinarily explained by some theory of 'borrowing.' But the general result of this paper is to show that the resemblances attributed to 'borrowing' are more truly to be attributed to racial immixture. And finally it will be pointed out that the general proof of definite relations between races and civilisations will be an important step towards establishing the laws of man's history.

APPENDIX.

A List of Works referring to British Mineral and Thermal Waters. By W. H. DALTON, F.G.S.

[A communication ordered by the General Committee to be printed *in extenso* in the Report.]

THE following list of some 740 works bearing upon mineral and thermal springs within the area of the British Isles is an extension of one compiled by Mr. Whitaker some years since, and placed by him at my disposal. It included only England and Wales, and I have endeavoured to render it a complete record of the literature of the subject, but have been compelled to take many titles at second hand, verification with the originals being often impracticable. For this reason also the magnitude of independent works is indicated in but very few instances.

I had purposed adding an index of localities, but that this would be too incomplete to be really useful is manifest from the consideration that many titles cover large areas and do not name places fully described in the text.

A similar bibliography of the mineral and thermal springs of the world at large is in preparation, and the manuscript will be at the service of any scientific body or individual willing to publish the whole or any geographical section thereof.

Notification of any omissions will be gratefully accepted.

My best thanks are due to my friends Messrs. G. J. Symons and W. C. Hazlitt and to my former colleagues, Messrs. W. Whitaker and H. B. Woodward, for their numerous and valuable additions and emendations.

A. Report.

The amount of material at present in the hands of the Committee does not yet warrant the preparation of a formal report with definite recommendations. The southern, eastern, and south-eastern coasts have been fairly well described in previous reports, and these districts are further illustrated in the old reports now printed. Information, however, is still wanted for the western shores of England. It is expected that this want will be supplied during the coming year, and that a final report may then be drawn up.

As the history of coast-changes can only be read by the light of definite information as to the conditions known to have existed at special periods, it is very desirable that the Committee should possess as much of such information as possible. Some important official documents are here printed, but there must be many such in the possession of public departments, harbour commissioners, local authorities, and private landowners. The Committee would be very grateful for copies of these, and indeed for any information bearing upon the subject.¹

¹ Communications for the Committee can be sent to the officers of the British Association, 22 Albemarle Street; or to the Secretary of the Committee, W. Topley, 28 Jermyn Street, London.

B. Memorandum.

By R. B. GRANTHAM, M.Inst.C.E., F.G.S., Chairman of the Committee.

The British Association Committee have received several reports from a Committee appointed by them upon the effects and power of the sea to erode or otherwise to destroy, or to accumulate land on the coasts of this island.

The Committee have published upwards of forty reports from those who, as engineers, geologists, officers of the Army and Navy, &c., have had special opportunities of observing the changes which are perpetually taking place on the sea-shores.

The inquiries which have, up to the present, been made will be continued upon the south and east coast, and will be extended to the west coasts. They are made by means of printed forms, which the Committee have issued in order to secure uniformity for investigating every change caused by the action of the sea.

The inferences to be drawn from such reports are important, as bearing upon the vexed questions of boundaries of land upon sea-coasts between those vested in the Crown, in lords of manors, and in owners of land; as to the accumulations of shingle and sand-banks, and the frequent shifting of the latter; and also as to the land on the sea-shores where slips occur and entirely change the positions of the frontages, and in many cases totally obliterate them.

Such an inquiry as this by the British Association will, when completed, afford information by which positions on the coasts may be selected for small harbours and fishing ports.

The reports will point out to what extent the removal of shingle has caused, and continues to cause, the constant erosion of the sea-frontages from the land, and will thus indicate the advantage or disadvantage of constructive works.

Mr. Hans Hamilton's interesting and valuable paper, reported in vol. xviii., part 6, of the 'Transactions of the Surveyors' Institution,' enters very fully into the state of the law and the history of the cases, quoting the opinions affecting foreshores, and opinions which have been given in the Courts on the rights and privileges both of the law and the practice of the numerous questions which have been dealt with. A discussion took place upon the paper, in which several members of the Bar joined and gave valuable information as to the powers of the Crown and reputed owners. Others took part in the discussion who had been practically engaged in local investigations in various parts of the kingdom on this subject.

The information in this paper, and the discussion upon it, together with the investigations of the Erosion Committee, will, it is hoped, hereafter form a valuable source from which those engaged in harbour and coast protection may derive much assistance.

I have been induced to prepare this Memorandum in order to point out what should be done by means of the Coast-Erosion Committee under sanction and instigation of the British Association, and the course which might be pursued to form a system of protection to the coast all round the country.

It appears most desirable that advantage should be taken of the results obtained by this Committee, and that attention should be paid to such cases of erosion of the sea-coasts as have been reported on.

The papers hitherto prepared are very valuable ; but they are unconnected, and do not give the means of enabling us to promote a system of protection on all parts of our coasts. It seems essential that the information, to be practically useful, should point out how a connected line of proceeding and operation could be formed to prevent the wearing away of land and the utilisation of the coasts by the formation of harbours of refuge for all kinds of protection of commerce, and local communication for trade and agriculture as well as for navy purposes, and for works for promoting intercourse for remote districts.

Two debates took place in the House of Commons in 1887 upon the question as to the means by which works adapted to this object might be carried out, and under the sanction and direction of the Government.

In the course of the discussion reference was made to a system by which the works should be carried out and conducted. It was stated also in the course of the discussions that it was not intended to cast any censure upon the Public Loan Commissioners, but it was intended to point out and indicate that in the opinion of the House the Harbour Department of the Board of Trade was as well qualified to deal with such questions, and to give a technical opinion of requirements and necessities of certain localities for harbours and public works, for the purposes of trade and other necessities, and for the security and wants of all classes.

Although the foregoing suggestions and remarks refer mainly to harbours, it seems desirable that the question should include large harbours, and shelters and defence works as well. Much benefit would result from the accommodation and protection of the fishing interests as well as from other facilities for trade if properly assisted and promoted.

C. Notes on the Coast-line from Penarth to Porth Cawl, in Glamorganshire.

BY HORACE B. WOODWARD, F.G.S., 1887.

At Penarth headland the cliffs are composed of the following strata :—

		ft.	in.
LOWER LIAS—Marls, limestones, and shales	(about)	100	0
RHÆTIC BEDS—Grey marls		15	0
Black shales		20	0
Grey marls	(about)	50	0
KEUPER—Red marls.			

The cliffs are nearly vertical and attain a height of 200 feet, the church a little way inland being 234 feet.

The mass of the cliffs is formed of crumbling marl, so that there is a constant falling of material, though on so small a scale that no great difference has been made in the course of the past twenty or thirty years. At the same time these small shoots of marl render it somewhat unsafe for anyone to walk close under the cliffs, or to linger there in geological study. The beds occupy a synclinal, slightly faulted in places, and broken and slipped near the pathway between Penarth headland and Penarth.

The beach is made up of fine grains of limestone and pebbles of Red Marl and Lias, also blocks of flat, more or less rolled, slabs of Lias limestone.

The beach slopes somewhat sharply in places, but no 'fulls' are observable. At Penarth headland the cliffs are protected by rocky ledges. The tide here rises from 20 to 22 feet.

At Penarth itself a sea-wall and promenade protect the beach for a short distance. To the south an inclined roadway extends to the summit of the cliffs, and this has been in part formed and protected by a bank of grey marl. The beach here at low tide, for three chains in width, is muddy ; and further seaward, for 6 or 10 chains, it consists of mud and boulders, resting on a platform of Red rocks.

In the railway-cuttings south of Penarth, not far from the cliffs, the lower beds of the Lower Lias have been exposed. It is noteworthy that not only are the beds of limestone much broken up here and there, but the broken-up masses of limestone are waterworn into forms as irregular as flints, although the surface soil is a stiff clay. During the summer of 1887 wide fissures were opened in the ground, cracks extending to a depth of 4 feet; and in this way rain-water would readily find its way through otherwise impervious strata into porous beds below.

North of Lavernock great cracks are formed in dry weather parallel to the cliffs; and these are sources of great weakness, leading to slips and gradual waste of the cliffs.

From Penarth southwards to Lavernock Point the beds shown are the same as in Penarth headland. The cliffs run north and south, facing the east, and while for the most part 50 feet high, they attain a height of 100 feet above the Roundbush Rocks, S.E. of Lower Penarth. They exhibit a synclinal to the south of Penarth, faulted to a small extent in four places. Further on the beds rise in an anticlinal, so that the Red Marls at one point form the entire portion of the low cliff. At Lavernock itself the beds dip sharply to the south, and the Lower Lias limestones and shales form the headland, with ledges of limestone protecting the coast and running out seaward. Alabaster was formerly worked in a 'cave' driven in the Red Marl at the base of the cliffs, about half-way between Penarth and Lavernock; but I was informed in 1887 that it had not been worked for about fifteen years.¹

Rock platforms are shown at low water along the stretch of coast from Penarth headland to Lavernock. At high water the sea ordinarily touches the cliffs at many points, and the headlands are impassable, including a projecting bluff of red marl overlaid by grey marl north of Lavernock. Along this portion of the coast the easterly gales alone produce much effect on the waters and cause damage to the cliffs.

The beach nowhere shows any great thickness of recent accumulations, but for some distance midway between Penarth and Lavernock there is much boulder-shingle at the base of the cliffs, and small patches of local detritus are shown here and there on the shelving rock-platforms. There is a spit of boulder-shingle at Runny Point.

From Lavernock Point the cliffs run south-south-westwards, and immediately west of the point are composed as follows, the heights being 50 feet at the point, and 110 feet further west:—

	ft.	in.
LOWER LIAS—Limestones and shales	25	0
Chiefly grey marls, with here and there stone-		
beds	40	0
Limestones and shales	35	0

The beds occupy a synclinal, the lower beds of limestone, &c., forming bluffs at either end of this stretch of cliffs, the grey Lias marls descending to the beach-level between. Platforms of rock and marl extend seaward for 8 or 10 chains at the foot of the cliffs, near which there is in places an accumulation of boulder-shingle and sand.

By Ball Cottage, south-west of Lavernock, there are reefs of Dolomitic conglomerate, with boulders of this rock on them. In the small bay to the north the beach comprises a little sand in places, but consists mostly of boulders of Liassic, Rhætic, and Triassic rocks, forming one slope. Under the cliffs, about 10 yards of this slope rise above the ordinary high water, then come 2 chains of beach, and reefs of rock (hard grey Rhætic marl) further out. The cliffs here are protected by shrubs.

Along this line of coast the westerly, south-westerly, and southerly gales are all very destructive, and their influence is shown in a marked manner on the trees and shrubs.

Sully Island is composed of red, pale buff and grey Triassic limestones and marls, gently inclined towards the mainland, resting on the upturned beds of the Carboniferous limestone. The severance of this island is due to the more rapid denudation of the Triassic beds, which now at low tide connect the island with the mainland, while the platform of Carboniferous limestone has better withstood the action of the breakers.

Barry Island is largely formed of similar rocks, with also Lower Lias and Rhætic beds. Owing to the recent dock-works it has been connected with the mainland. The Carboniferous limestone has a seaward dip, and forms the two horns or headlands of the island and the promontory just to the west. The severance of the island was owing

¹ See Section in *Proc. Geol. Assoc.* for 1888. Excursion to South Wales, &c., p. 32.

to the denudation of the softer Rhætic beds and Red Marls, which connected the island with the mainland towards the north-east, while northwards and westwards the river channel has been widened by tidal action. The cliffs south of Barry Island rise to a height of about 50 feet. Whitmore Bay, on the same side, between the two headlands, is a beach of sand and shingle at low tide. North of it a little blown sand occurs on the face of the slopes.

From Cold Knap, west of Barry Island, where the Carboniferous limestone is exposed, the cliffs are about 50 feet high. Thence to St. Donat's the general direction of the cliffs is east and west; they are formed of the Lower Lias limestones and shales, but essentially of limestone. The beds have, on the whole, a slight easterly dip; but this is counteracted by numerous small faults, so that the same beds are presented to our view, undulating here and there, and dipping now and again in other directions.

East of Porthkerry the cliffs rise to an elevation of nearly 200 feet, and they attain a similar height on the west. Further on, as far as East Aberthaw, the cliffs are under 100 feet, and in some places not more than 50 feet. At high water the sea washes the cliffs along the greater part of this distance, but for a short extent east of Pleasant Harbour, East Aberthaw, there are wooded cliffs some little distance (about 300 yards) from the high-water mark of ordinary tides. The interval is occupied by alluvium, covered here and there with patches of shingle; beyond is an expanse of shingle, extending another 300 yards to low-water mark. But the shingle is of no great thickness, and is based on mud and Lias rock. Eastwards the coarse shingle stretches along the base of the cliffs over ledges and platforms of Lias.

The alluvium before mentioned indicates that the river Ddaw formerly flowed out to sea further eastward than it does now.

West of the port of Aberthaw there is an expanse of alluvial ground protected by embankments. This is bordered by hillocks of blown sand, and these rise about 20 feet above the shingle beach. Bordering the blown sand there is a ridge of thick shingle, and beyond this, between tide-marks, is an expanse of shingle on mud, with sand here and there.

The shingle consists of rolled pebbles and boulders of blue Lias limestone, and it is these stones which constitute the celebrated Aberthaw lime. All the 'lime' taken away has been shipped in the form of pebbles or boulders, taken preferably between high and low water mark; for these stones are considered to yield a better lime than those heaped up at a higher level, and which have been exposed to the sun's rays, &c. Stones from this latter position are, however, employed locally in the lime-kilns. I was informed in 1887 that fifty or sixty years ago there used sometimes to be about twenty vessels in the harbour loading with beach pebbles. Since the introduction of railways, limes from other districts, such as Harbury, Rugby, &c., have to a great extent diminished the trade at Aberthaw.

The material has travelled from the west, and owing to the encroachments of the sea it has been heaped on to old alluvial ground—portions of the old estuary of the Ddaw. In the blue mud that here covers the platforms of Lias, on both sides of the present river, the occurrence of *Scrobicularia plana* was noticed by Mr. H. W. Bristow. He observed that the mud was from 8 to 10 feet thick in places; and intervening between it and the Lias there is, south-west of Gilston, a bed of white calcareous tufa, with land-shells (*Helix*); a bed which he noticed also at Tresilian, in that case directly under the shingle.

There are no cliffs for some distance west of Aberthaw, not in fact until we approach Summerhouse Point. Thence to Dunraven the cliffs are formed of the Lower Lias limestones, with subordinate layers of clay and shale. They vary in height, attaining a maximum elevation of 235 feet at Whitmore Stairs, between Nash Point and Dunraven, and overhanging in places west of the Summerhouse, where the dip of the strata is seaward.

The beach consists of ledges and platforms of Lias rock, from 150 to 200 yards broad or more, covered here and there by coarse boulder-shingle of Lias rock and occasionally by sand. South-west of Llantwit-Major the Lias strata on the foreshore are much jointed, and the sea works off huge masses of rock; here there is a great bank of boulders. Where the stream from Llantwit flows out to sea a peaty deposit, containing nuts, leaves, and twigs, was noticed by Mr. Bristow. This bed rested on blue clay with *Scrobicularia*, beneath which there was a deposit of tufa. The whole was overlaid by boulders and shingle. Here and there along the coast great falls of the cliff take place; at other points, as at Tresilian, there are caverns, which tend to show that in certain places the cliffs have not recently suffered great destruction.

At St. Donat's large rounded blocks are taken away from the beach, to be used as building-stone and occasionally for lime-burning.

West of St. Donat's there are fine level platforms of rock on the foreshore. Here the cliff follows the strike of the strata, but the ledges naturally vary much along the line of coast, according to the inclination of the strata and the changes in the direction of the coast.

South-east of Nash Point, between the two lighthouses, the cliffs have suffered noteworthy losses by slips and falls of rock. Here, for a short space, a wall has been built to protect the higher lighthouse.

South-east of Dunraven, the ledges and platforms of Lias rock, covered in places by sand, may be seen stretching out rather more than a furlong seawards at low tide. Considerable slips of rock have taken place, and accumulations of tumbled blocks and boulders are to be seen here and there along the foot of the cliffs.

At the Witches' Point, Dunraven, the lowest beds of the Lower Lias are unusually hard and more or less conglomeratic, and they rest irregularly on the upturned edges of the Carboniferous limestone. A prominent headland has been the result, and there are three caverns on the south side of it in the Lias. To the north-west of this headland there is a fine expanse of sapsl between tide-marks, while the coast is bordered near the Lodge, Dunraven, by very coarse boulder-shingle.

The cliffs in the north-eastern angle of the bay, under Dunraven Castle, show the Lias strata much disturbed and faulted, and here considerable slips take place. I was informed in 1887 that ten or twelve years ago there were caverns here, but no trace of them remains.

From Dunraven, past Southerndown, to Sutton, the cliffs are formed of the ordinary Lias limestones and clays, dipping eastward, but undulating under Southerndown. These beds rest on about 90 feet of hard blue conglomeratic Lias, and hard white and conglomeratic rock, known as the Sutton stone. These lower strata here, as well as south of Dunraven, stand out in massive beds, and offer greater resistance to the breakers than do the ordinary beds of the Lower Lias. They rest irregularly on the Carboniferous limestone; and partly from this fact, and partly owing to great joints and fissures in the rocks, numerous caverns have been excavated by the sea. In one place below West an outlying stack of the Sutton stone, &c., stands out on the foreshore. The cliffs rise rapidly from the beach south-east of Southerndown to an elevation of about 150 feet near West, but decrease again further on to below 50 feet as far as the mouth of the Ogmore. Under Southerndown there are two or three faults where the beds are slightly displaced, and the cliffs stand out in wall-like buttresses.

The Black Rocks, west of Southerndown, are formed of Carboniferous limestone, much fissured, and worn into irregular shapes by the action of the breakers. Both in this rock and in the harder beds of Lias, deep channels, basins, and tiny arches are excavated by the waves dashing over the rocks and then draining off in lines of jointage, &c. Curious honeycombed surfaces are produced in the rocks by the combined action of the breakers and the spray. Here and there little sandy bays occur among the rocks, while more sand and shingle are exposed at low tide near Sutton, the shingle containing pebbles of red and brown Coal-measure grits, as well as pebbles and boulders of Carboniferous limestone: no doubt deriving many stones from the river, which brings material from the South Wales coal-district, while some of the boulders are derived from the Dolomitic conglomerate.

The low cliffs here consist of Carboniferous limestone, with thin and irregular cappings of Lower Lias (white Sutton stone and conglomerate) near the Black Rocks, and irregular masses of Dolomitic conglomerate further on.

Near the mouth of the Ogmore, and on both sides of it, the Carboniferous limestone and Dolomitic conglomerate are smothered up over considerable areas by blown sand. This extends by Candleston Castle and forms the Newton Burrows, which stretch towards Newton Nottage and Porth Cawl. Not far from the mouth of the river is the Tusker Rock, an islet of Carboniferous limestone that is ordinarily exposed at low tide.

D. Notes on the Coast from the Wyre to the Ribble.

By A. DOWSON, 3 Great Queen Street, Westminster.

The part of the coast to which my remarks refer extends from the mouth of the Wyre, near Fleetwood, to the northern side of the estuary of the Ribble, near Lytham.

I am well acquainted with this coast, as I designed and superintended the erection of a pier in the estuary of the Ribble; I also had to prepare evidence relating to the removal of shingle from this district; and I surveyed the northern half of the estuary of the Ribble for the Parliamentary Inquiry with Reference to the Ribble Navigation Act of 1883.

The total length of coast is about 16 miles, Blackpool being situate about half-way. About 11 miles of the coast below Rossall Point lies north and south, but the remainder curves round eastward towards Lytham.

The flood tide runs up the St. George's Channel from the south, past Blackpool on to Fleetwood; but part of it turns off eastward on striking the northern side of the Ribble estuary. Spring tides rise about 28 feet.

The district generally is flat and sandy, the level not being much above high-water mark; but north of Blackpool there are cliffs composed of loose clay, which after the rains and frosts of winter frequently slip. Southward of Blackpool the coast consists of extensive sand-hills varying in height from a few feet to 50 or 60 feet.

The whole foreshore consists of fine sand of very varying widths. Towards high-water mark there is a belt of shingle (largely composed of granite), the pebbles varying in diameter from 6 inches and under.

This stretch of coast being bounded both north and south by a river, the whole supply of shingle (except that washed from its own cliffs) is cast up from the sea on to the shore above Blackpool by westerly gales. It is then caused to travel past Rossall Point to the Wyre by winds from the south, or past St. Anne's towards the Ribble by winds from the north.

This almost ceaseless supply of shingle leads to an immense accumulation at the northern and southern limits, the name of 'Tully Bank' being given to the former, and 'Double Stanner' to the latter. This growth has been going on from time immemorial, as is shown by a large portion of the new watering-place known as St. Anne's, being built on some of the old ridges of shingle, which are nearly 2 miles eastward from where the ridges are now being formed.

At *Rossall Point*, and for about 3 miles south, timber groynes have been erected at frequent intervals. The scouring is, however, very great, and it is only by constant renewals that the sea is kept from encroaching. The bank at the shore ends of the groynes is frequently hollowed out by the waves having been made to run along the sides, and in many cases I have found it easier to pass under the bottom planking of the groynes rather than to walk round by the bank.

The 'Rossall Landmark,' which is an octagonal structure of considerable height, was built by driving timber piles into the beach. In time this beach became so scoured away that, to render the 'Landmark' secure, new piles were driven deeper alongside the old ones, to which they were bolted. At my last visit to this place I found that the second set of piles were themselves being left bare, showing that in spite of all the groynes in the neighbourhood the lowering of the foreshore continued.

A heavy sea embankment built to protect the grounds of Rossall School was also seriously damaged by the sea.

Blackpool was originally a small fishing village, having a large quantity of shingle in front of it, and any damage done by the sea was at once repaired by the person most interested, with the aid of his immediate neighbours.

In course of time a rough stone footing was built to protect the cliff, and from this date the shingle began to be driven away.

The increase in the size of the town led to the making of a sea-wall, or what is locally known as a 'hulking,' by sloping the front of the shore to about an angle of 50 degrees and paving it with stones. This wall was so undermined by the sea that the foundations had to be carried down to a lower level. The sea then had a longer incline up which to run, and of course to rush down again, striking against the beach at the bottom and wearing it away. A second time this wall has been carried lower, with the result that still heavier seas came against its face.

A proof of this is that the surface of the foreshore is now several feet below what

I knew it to be twenty years ago. This was shown by some of the foundation screws of the piles of the pier having been washed bare.

The ordinary cost of keeping the present sea-wall in repair amounts to over 1,500% per annum, in addition to which much loss and anxiety are frequently caused during a heavy storm.

Attempts have been made to replace the shingle driven away by the wall, by erecting timber groynes. The result is that shingle may sometimes be found on their north and sometimes on their south sides, but never during heavy weather can any reliance be placed on an accumulation to assist the sea-wall. The general level of the beach is not in the least raised; the seaward ends of the groynes have deep pools of water around them, and the waves driven along them to their shore ends have struck heavily against the wall and have greatly worn the stonework. It is only by very constant attention that the wall is maintained.

Whilst this damage continues to be done at Blackpool thousands of tons of shingle are driven past it, as before described.

St. Anne's, a new watering-place near the most northern boundary of the estuary of the Ribble, is built on what was a few years ago a rabbit-warren, underlying it being the old shingle ridges before mentioned.

When the town was first laid out a sea-wall, smaller, but of similar outline to the one at Blackpool, was built, much shingle being left between it and the sea. Soon after its erection the shingle began to be driven away, and it became necessary to lower the foundations several feet, as was found to be the case at Blackpool.

Many attempts have been made to protect the wall by groynes constructed of timber, but the invariable result has been to produce an increased scour. I have myself made several attempts, but it was not until I discarded solid groynes and substituted open ones that I met with any really good result.

After various modifications I put up several open groynes at right angles with the wall, their sides or panels being made of wrought-iron gratings, so as to retain the shingle while allowing the water to pass through them freely. These produced a very considerable accumulation of shingle, which after several years still remains there.

Subsequently, during a heavy gale, a considerable length of another portion of the wall was undermined, and, as it was in imminent danger of being washed down, I fixed several open groynes in front of it. The result was that after the next rough tide a large quantity of shingle was trapped. Then, as the groynes became buried, they were lifted up from time to time, so that this part of the beach was raised from 10 to 12 feet above the level which existed when I commenced operations, and the wall has since remained safe.

After this experience the owners of the property were so convinced of the benefit derived from having the open groynes erected that they purchased from me the right to place them along any part of their frontage (about one mile). Having afterwards learnt that they were about to erect a number of short groynes, I pointed out that they would not be likely to attain their object. Short groynes could only lead to the formation of a narrow and steep incline of shingle, whereas they should strive to accumulate a broad, flat incline upon which the waves would break before reaching the sea-wall. They did not, however, carry out this suggestion, so that I fear little good can be expected from these additions.

The foregoing evidence appears to me to show—

(a) That a sea-wall causes the shingle in front of it to be driven away.

(b) That solid groynes, especially if high ones, are most mischievous, as owing to the scour they produce during heavy weather they drive the shingle seawards.

On the other hand, with open groynes it is impossible for the shingle to be driven away, and in practice they have retained it for several years, where it still remains.

E. Notes on the Coast of Durham, between the rivers Tyne and Wear,

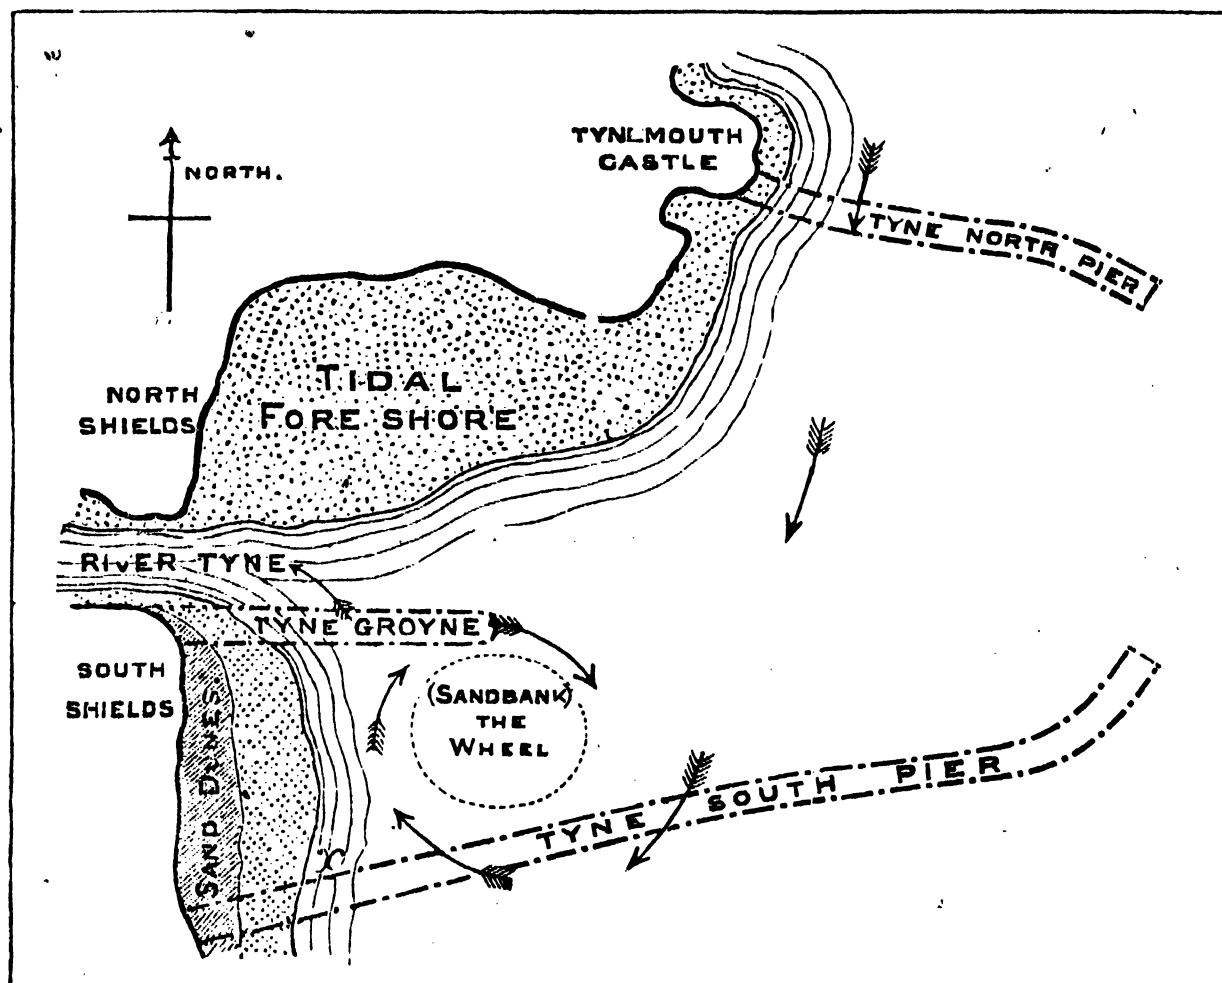

By HUGH BRAMWELL, The Whitburn Coal Company, Limited, South Shields.

2. The nature of the coast is as follows:—a. $1\frac{1}{2}$ mile of sand immediately south of the Tyne; 4 miles of limestone cliffs (magnesian limestone Permian); 1 mile of sand, the Whitburn sands; $\frac{1}{2}$ mile of limestone cliffs

the Roker cliffs; $\frac{1}{2}$ mile of sand, the Roker sands, extending to the Wear.
b. Greatest height of cliffs, 80 feet; minimum height of cliffs, 20 feet; average height of cliffs, 40 feet.

- 3.** The coast-line runs roughly north and south.
- 4.** The prevailing wind is westerly.
- 5.** The north-east wind is the most important in raising high waves and in the piling up or the travelling of shingle. There is, however, but little shingle, except in the small creeks.
- 6.** The tidal current 'flows' from the north, and 'ebbs' back to the north. The 'flow' is much the more powerful.
- 7.** Spring tides range $15\frac{1}{2}$ feet, neap tides range 11 feet. The greatest exposed area is near Whitburn village, where from 200 to 300 yards of foreshore are exposed. Along the cliff-portion of the coast there is deep water to within 100 yards of the cliff.
- 8.** The area covered by the tide consists of sand at Shields, Whitburn, and Roker; bare rock along the cliff-portion of the coast. A certain amount of shingle accumulates above high-water mark along the cliff-line in the small creeks. There is also an accumulation at the south end of the Whitburn Sands.
- 9.** Such shingle as there is travels to the south. The amount is undoubtedly larger at the southern portion of the coast-line under notice.
- 10.** The amount of shingle probably remains constant, or nearly so. It may be increasing at the south end of the coast-line.
- 12.** The Tyne Commissioners' groyne is the only one built with a view of preventing the movement of shingle, sand, &c.; its object being to prevent the sand filling into the dredged channel of the Tyne. The Tyne Commissioners' south pier extends 1,650 yards (present length) into the sea, and it has caused an accumulation of sand immediately to the south of it. This sand-deposit is not covered by the ordinary high tides, but spring tides, especially if accompanied by north-east winds, rise over it. The Wear Commissioners' old pier, being only 270 yards long, has not led to any appreciable accumulation of sand. A new pier is, however, in course of construction at Roker, to extend some 600 to 800 yards into the sea, which will most probably lead to the piling up of shingle and sand on its north side by preventing their passage to the south.
- 13.** At South Shields the Tyne Plate Glass Co. remove large quantities of sand, both from above high-water mark (sand-dunes) and also from the more recent accumulation, now only covered by exceptional tides. The sand is used for grinding the sheet glass. A small amount is also removed from the Whitburn Sands, for building purposes, under permission of Sir Hedworth Williamson, the lord of the manor. The Tyne Commissioners have also worked an immense quantity of limestone from quarries on the cliff-line for the construction of piers, &c. The operations have, however, been confined to above high-water mark.
- 14.** **a.** The cliff-line is, no doubt, being worn back, being fully exposed to heavy seas from the north and east without any protection whatever, the base of the cliffs being high-water mark. **c.** The limestone, however, being comparatively hard, especially some beds, the wear is very small. After every winter, however, there are numerous falls of stone, due to frost, &c. Estimating that 150 tons of stone fall from the cliffs each year, the average wear of the whole cliff-line would be 1 inch in fifty years. **d.** The Lizards Common, which extended along two miles of the cliff-line, was inclosed in 1718. I have examined the award plan and compared it with the Ordnance Survey of 1854, and find that the loss of land during that period is inappreciable on the plans. A footpath was, however, left along the whole cliff-line, outside the enclosure walls, and in several places the cliff has fallen away, and either carried the path away or rendered it unsafe, and a new path has been made by encroaching on the enclosed land, inside the original line of wall.
- 16.** No land is being gained, beyond the increase of sand behind the Tyne south pier, which is, however, still subject to inundation.
- 17.** There are sand dunes at South Shields and at Whitburn. **a.** Locally known as 'bents.' **b.** At Shields they are from 8 to 12 feet in height. At Whitburn their extent and height are very limited. **c.** The Shields dunes were formed before the commencement of the piers, and were probably caused by the tide flowing south, and sweeping past Tynemouth point across the river

mouth, causing a back current from the south (as per sketch). **d.** The sand dunes are not increasing, and they have to a large extent been removed (see **13**), and parts have recently been converted into parks. **e.** The dunes are grass-grown, and the sand does not blow over the adjoining land to any extent.

NOTE.—Arrows denote tidal currents before the building of the piers, causing a deposition of sand at *x*.

- 19.** The Tyne piers completely stop the travel of any shingle from the north to this piece of coast. All the shingle accumulated in the little coves consists of débris from the limestone cliffs and from the boulder clay, which in parts covers the limestone. The north end of the cliff-line is consequently more destitute of it than the south end. The largest accumulation, and, in fact, the only deposit affording any protection to the coast-line, is at the south end of the Whitburn Sands. Near the middle of the Whitburn Sands, at the mouth of a small stream, there are indications of a submerged forest, in the stumps of old trees *in situ*, now below or near high-water mark. These were, however, covered with sand when last I examined the locality.

F. Reports to the War Department and to other Government Departments on Various Parts of the South-eastern Coasts (1856-1867).

By J. B. REDMAN, M.Inst.C.E., F.G.S., F.R.G.S.

(Printed by permission of the War Department.)

1. SANDOWN CASTLE.

The Secretary of State for War to the Mayor of Deal.

War Office, Pall Mall, April 1857.

SIR,—1. On the 4th September last your predecessor addressed to the Secretary of State for War a Memorial of the inhabitants of Deal upon the subject of the danger which is apprehended from the ravages of the sea upon the high shingle beach, which, until recently, has formed a sufficient barrier between the sea and the town of Deal, together with adjacent properties.

2. At the same time communications were received upon the same subject from Mr. Stephen Pritchard and Mr. William Betts, two neighbouring proprietors.

3. From these communications it would seem to be generally admitted that the sea was advancing by degrees upon the land; and at the same time an opinion was expressed that part of the injurious action was due to the construction of groynes in front of Sandown Castle.

4. An inquiry was thereupon instituted by order of the Secretary of State, by which it would seem that the lowering of the groynes would be of little or no advantage to the security of the neighbouring beach; but as, at the same time, they seemed to be of little advantage to the Castle itself, the Secretary of State ordered them to be lowered, as was communicated to you in a letter from this Office of the 4th November last.

5. It was pointed out in that letter that it could scarcely ever be possible that the measures taken by one proprietor should be those best calculated for the general interests of the neighbourhood, when all are threatened with the same dangers; and the Secretary of State expressed his perfect readiness to subordinate the measures taken for the protection of Sandown Castle to any general measures which may be adopted for the protection of the coast.

6. As the Secretary of State did not hear that any such general measures were in contemplation, and as it was a matter of importance to determine what was the best course to adopt with reference to Sandown Castle, his Lordship, after consulting with the Inspector-General of Fortifications, ordered that the subject should be referred to Mr. Redman, a civil engineer of considerable experience in works of this description.

7. Mr. Redman has made a searching investigation into the whole of the circumstances, and has presented a valuable report, which, as it is of equal and, indeed, greater interest to the neighbouring proprietors than to this Department, has been printed for general information.

8. As the present letter will explain the circumstances under which Mr. Redman's report was made, the Secretary of State has directed that it should be printed with the report.

9. Twenty-five copies of the report are herewith transmitted for distribution among the landholders most interested, and additional copies will be forwarded, should you require them.

10. The perusal of this report, and, indeed, the mere inspection of the plan, is sufficient to show that the further maintenance of Sandown Castle must in any case be difficult, and will be quite impossible unless the neighbouring proprietors are willing to incur the expense of general measures for the defence of their respective properties.

11. If those measures are undertaken, the Secretary of State will provide in the Army Estimates for that proportion of the works recommended, which will cover the property of this Department.

12. If they are not undertaken, Sandown Castle will be dismantled, and no future expense incurred on its maintenance.¹ The military value of the Castle is but secondary, and, though interesting from historical recollections, the Secretary of State does not consider he would be justified in incurring the expenditure recommended by Mr. Redman at p. 11 of his report [p. 910] for Sandown Castle itself, as those measures would only be of temporary assistance, and would entail constant additional expenditure as the sea advanced on either flank of the Castle, and would ultimately swallow it up.

13. On the other hand, if the general measures suggested by Mr. Redman at p. 14 [p. 911], or other measures of an equally general character be adopted, there may be a fair chance, not only of maintaining the Castle, but of saving the whole neighbourhood from the peril to which it now seems to be exposed.

The question must now be left to be decided by the landowners, who may obtain a local act for the purpose, or set on foot any other collective action they may think best; and the Secretary of State hopes that you and they will give him the credit of having endeavoured, to the best of his power, to afford to the neighbours of the War Department property at Sandown Castle as much assistance as it is in his power to afford.

I have the honour to be,

Sir, your obedient Servant,

(Signed)

B. HAWES.

Mr. Redman to the Secretary of State for War.

5 New Palace Yard, Westminster, December 20, 1856.

SIR,—In pursuance of the instructions contained in your letters of the 3rd and 14th ultimo, and accompanying memoranda of latter date, I visited Deal from the 25th to 29th ultimo, and for the information of the Secretary of State for War beg to report the result of my inquiries, and what appears to me would be the best plan of defence to adopt to stop the continued encroachments of the sea; in illustration thereof I beg to refer to the accompanying plan and sections, which show the state of the shore north and south of the Castle, and northward to Battery No. 1, during my survey, as also the works I propose should be executed.

On the morning of the 25th ultimo, at high water, with a high tide, and the wind from N.N.W., I found the sea breaking over the Castle, and over the outer brick walls of Battery No. 1, and the Castle moat was full of water, the sea getting through the moat wall on the south side at the termination of the new wall; this was subsequently repaired; at the same time the sea was making a clear breach through the crest of the beach south of the 'Good Intent' public-house, and running into the adjoining fields, and north of the Castle nearly up to Battery No. 1 the sea was over the saltings behind the shingle mole and sand dunes, forming a small lake right up to the adjoining fields, coming in south of Battery No. 1, through two breaches in the crest of the shingle, and flowing round the back of the officers' quarters, or south Tower.

The condition of the shore from the north side of Deal to half-way between the two batteries is very serious, and should there be a continuance of gales from N. and N.E. during the winter, it is difficult to estimate the probable consequences, not only to the property of the War Department, but also to the north side of the town of Deal and the adjoining land.

The inroads made upon the shore between Sandown Terrace and the Castle are so extensive that should a permanent breach occur there, which is not at all improbable, the north side of the town would be threatened as well as the adjoining low lands, or should the wasting of the beach continue, adjoining Battery No. 1, the whole of the low lands up to the line of railway, and even beyond, might be submerged.¹

From the information I have been able to gather, it would appear that the whole of the shore from Sandown to midway between the two batteries has been encroached on by the sea during the last eight years at an alarming rate.² It would appear that at Battery No. 1, only four years back, the line of beach was 40 feet to 50 feet seaward of the battery, and now it is in a line with the back of the gun racers. As the sea has gained on the land, the beach has not only diminished in quantity, but has travelled landward, gaining on the sand-hills, which now in places crop out through the shingle and are washed away by the sea.³ The result of this action is that the upper 'full' of shingle is travelling to the rear of the Castle and Battery, and leaving the groynes, the western ends of which are buried in its progress by this landward recession of the shingle. From the greater prevalence of N.E. winds during the last seven or eight years⁴ on this part of the coast, the leeward motion of the beach has been to the southward; as, however, this mole of shingle travelled originally from the southward, should S.W. winds again predominate to a greater extent the re-accumulation of beach may be looked for, and a motion to the northward, for we find that at Battery No. 2, where at present there is an absence of modern shingle, which almost ceases shortly north of it, there are two 'fulls' of beach after S.W. winds.

There are two deep pools of water behind the beach north of Battery No. 1, which did not exist seven years back; evidence of the encroachment of the sea.

From half-way between the two batteries to Battery No. 2 the mole of shingle appears to have been tolerably stationary for the last eight or nine years, but to the southward the shingle has constantly diminished over the same term of years, and about 20 feet in breadth of beach, according to local evidence, was eaten away at one tide by a breeze from the N.N.W. only a fortnight prior to my visit, the absence of

¹ [This, in effect, took place December 1862.]

² [Beach now gone back 150 feet N. of Castle, February 1863.]

³ [Receded 100 to 150 feet in 6½ years after this, viz., to February 1863.]

⁴ At Ramsgate, from the Harbour Register there, the excess of west winds from 1846 to 1856 has been an average of forty-six days per annum as compared with eighty-five days per annum from 1836 to 1846.

mischief northward being due apparently to the protection afforded by the Isle of Thanet.

During the degradation of this particular length of coast the beach south of Deal at Walmer and Kingsdown appears to have somewhat increased, though not at the same rate as formerly; this at first appears anomalous, but as Kingsdown, where such an extraordinary accumulation of shingle has taken place, is half-way between Dover and Sandown, it appears to have benefited by the motion of shingle from the southward and westward, or from the northward.¹

To show the extreme peril that the lands to which this mole of shingle has hitherto acted as a barrier are now in, it is only necessary to refer to the fact that these formations, in such a situation as this, when in equilibrium, are usually about 10 feet above the range of high water of spring tides; at the end of the esplanade the bank is 11 feet above this level; opposite the mill, 9 feet 9 inches; 500 feet north of the esplanade, 7 feet 8 inches; 800 feet, 7 feet 3 inches; and adjoining the 'Good Intent,' it is only 6 feet 3 inches above this level; north of the Castle the crest is usually from 8 to 9 feet above, until we come to the partial breach at 1,500 feet northwards, where the shingle and sand are only 6 feet above high tides. North of this there are even worse places, being only from 3 to 4 feet above at 1,700 and 2,000 feet northwards; and at one particular place, viz., 2,165 feet north, where there is a sudden dip caused by the breach of 25th ultimo, and the sand-hill cropping through the crest, it is only level with the range of high spring tides, viz., 19 feet above Datum, which figure deducted from those on the crest on plan, will give the relative heights above high water extreme spring tides. South of Battery No. 1 the beach where it has spread over the land is equally low, being only from 2 feet 6 inches to 3 feet above. North of the Battery we find the crest again from 8 to 9 feet above high water.

In reference to the first item of your instructions, viz.:—

'What are the best measures for preserving Sandown Castle from destruction?'

I beg to report that I consider the only effectual way of doing this would be by paving the bays between the groynes with stone, at a slope of about 7 to 1, terminated by a curved face meeting the base of the Castle walls, the margin next the sea to be sheet piled, or protected by a toe of large stones laid in a deep trench. At first it might be sufficient to protect the two bays adjacent to the centre groyne in this way; should no accumulation take place in the north and south bays, an extension of the paving would be necessary; but as I consider these groynes act injuriously by their great height, creating cross eddies and overfalls which sweep out the shingle after it is deposited, I recommend the planks of the north and south groynes being removed to the mean level of the beach north and south of these defences, and the planks of the centre and intermediate groynes to the level of the adjacent shore; the effect of this had best first be tried before encountering the expense of paving; a wall should be erected north of the Castle to the extent of your boundary to check the beach, and this might serve as an example to the landowners, or the revetment should be raised: this is imperatively required, likewise at the Battery, to prevent the beach retreating on the land, which, in travelling westward or landward and southward, at the same time, is heaped up against the walls of the Castle and Battery, and were counter walls, sufficiently high, erected in the directions shown, they would have the effect of driving the shingle seaward of these defences. No permanent benefit would, however, result from this without the wall was made continuous from the Castle to the Battery, and from this latter northward to where the beach is stable or unaffected by this landward motion; for should short lengths only be executed to the limit of the property of your Board, the shingle would drive past, and eventually the ends be undermined, as we now see in operation at the end of the esplanade wall at Sandown, which will shortly render the continuation of this wall imperative unless a re-accumulation of beach hereafter takes place.

A good deal of mischief is done by the sea getting inside the moat, and at low water finding its way out again under the foundations, which in all probability was one of the causes of the failure of the former cross walls. I would recommend (if the material could be readily found) that the moat should be filled to the level of the

¹ The degradation of the shore from St. Margaret's to Dover is almost as remarkable as in the district now under notice.

[February 1863: Notices from Her Majesty's Board of Works now posted against removal, consequent on loss of beach at S. Foreland, Sandown, &c. ? Admiralty Pier, Dover.]

lower embrasures, at which level self-acting tidal-flaps should be introduced in each of the cross walls to allow the water to drain out of the moat at low water, but to shut back against the ingress of the sea.

In the second bay from the north the footings of the north-east tower of the Castle are exposed, and in the third bay the footings of the south-east tower, and a water-worn substratum of hard sand, closely approaching sandstone in appearance, upon which the walls were originally founded, and which may be traced up the coarse vertical joints, and adapting itself to the irregular beds of the stones, precisely similar in character to the serrated edges of the sand dunes that crop out through the beach to the northward.

During the first day of my survey, viz., on the 25th ultimo, from 15 inches to 21 inches in vertical height of this sand were exposed to view at low water, but on the 29th only from 6 inches to 12 inches, from a slight accumulation of shingle having taken place in the interim, arising from the change of wind to the westward.

The paving of the proposed stone slopes should be laid on a bed of concrete or clay to prevent the recoil of the wave drawing away the shore from under the stone-work after getting through the joints, and this should be carried well up to the exposed footings of the Castle walls to prevent the sea having access thereto.

I estimate the cost of these stone slopes, if confined to the two bays north and south of the centre groyne, at 400*l.*, and if extended to the whole distance between the north and south groynes, 800*l.*

As regards the 'probable effect upon the land of the neighbouring proprietors,' I consider that such a system, coupled with a lowering of the Castle groynes, would be beneficial, as allowing a freer passage of the shingle north and south.

In making this survey and report I may, perhaps, have somewhat exceeded the precise limits of my instructions of the 14th ultimo; but looking to the tenor of your first letter of the 3rd ultimo, referring to 'the Coast between Deal and Sandown Castle,' and arriving as I did when the sea had breached the beach, both at Sandown and at Battery No. 1, it appeared to me, viewing the general waste going on over so great a length of coast, that it was impossible to report on the defences of the Castle without having reference to the whole length of the coast affected, and difficult to disconnect the consideration of the works necessary to be carried out for the protection of your defences and those for the adjoining properties, for an abandonment of the Castle would necessitate the construction of a sea-wall in the line of the beach, or the entire abandonment of the present line of coast, for the ground on which the Castle stands has gradually assumed the appearance of an island. Should the degradation of the coast cease, and a prevalence of south-west winds again renew the beach, such a step might be regretted.

As regards the coast from Sandown Terrace to the Castle, the only effectual mode of defence appears to me to be the erection of a sea wall in continuation of the present esplanade wall from the southward: this affects more immediately the Archbishop of Canterbury and the town of Deal.¹

From the Castle to Battery No. 1, should the present waste continue, to preserve the low lands from inundation, I should recommend the erection of counter walls of earth behind the beach, with a stone slope similar to what I propose for the defence of the Castle, and the consideration of this is also a landowners' question; Romney Marsh, formerly protected by a shingle beach and by groynes, is now defended by a stone slope. Such a work might be executed in lengths behind the thinnest and weakest portions of the beach, and the execution of the paving might be deferred until the beach, which would form a barrier as long as it remained, had been carried away and exposed the counter wall; it might eventually be necessary to extend such a wall northward of Battery No. 1, respecting which latter work I would recommend a similar course to what I advise at the Castle, viz., a lowering of the planks of the north and south groynes, and the extension of the latter westward up the crest of the beach, and the entire removal of the whole of the planks of the two intermediate groynes, which, from their direction and form, are not calculated to arrest or retain the shingle: it would also be necessary to construct a timber revetment or wall from the south side of the battery to the west end of the south groyne, and on to the extent of your property.

At Walmer and at the Admiralty premises at Deal notices are exhibited forbidding the removal of shingle, and this should be strictly enforced along the length of coast under consideration. Large quantities appear to be removed for various

¹ [Now flooding with shingle, February 1863.]

purposes, notwithstanding a notice forbidding its removal, in front of the Archbishop of Canterbury's property, and the attention of the authorities at Deal should be called to this pernicious practice.¹

The works I should recommend to be first executed at the Castle, viz., the alterations of the groynes, and the paving of the two centre bays, would probably amount in the aggregate to 450*l.*, and if the moat were partially filled and two sea sluices were added a further sum of 100*l.* would be required.

The works at Battery No. 1, exclusive of sea walls, would cost 100*l.* •

Sea walls behind the mole of beach would cost, say, 300*l.* for the Castle frontage, but these would be useless without being continued as the beach retreated.

From the way in which the shingle is now travelling, I consider that no system of groyning will produce any permanent benefit, and would only lead to disappointment.

In the event of a continued recession of the coast-line, and no steps being taken by the landowners for its protection, it may ultimately be necessary to abandon the sea faces at Sandown Castle and Battery No. 1;² but after a very careful consideration of the question, I should recommend the execution of the proposed works in the first instance.³

Before determining on the character or extent of works, it appears necessary to ascertain the views of the adjoining landowners.

As the wind had been blowing for ten days or a fortnight from the southward and westward I again visited the Castle on the 15th instant, and found a large lower 'full' of shingle had been thrown up from Sandown Esplanade to the Castle, and a considerable quantity of shingle had collected in the north and south bays, in the former of which the 'full' of shingle was highest on the south side of the north groyne, showing the motion had been reversed; the beach around these groynes was, however, being quickly drawn away by the change of wind to N.W. on the 14th.

I have the honour to be, Sir,

Your very obedient Servant,

(Signed) J. B. REDMAN.

2. SHEERNESS SEA-DEFENCES.

To Major Jervois, R.E.

5 New Palace Yard, Westminster, S.W., August 20, 1857.

SIR,—On the 3rd instant I was favoured with your instructions from the War Office to survey the sea-wall which bounds the property of the War Department at Sheerness, and to report, for the information of the Secretary of State for War, the mode in which I would recommend the works of renewal of the groynes, which form a part of these defences, should be carried out, and for which a sum had been voted in the Estimates for this year.

I accordingly proceeded to Sheerness on the 5th instant, as you stated it was desirable I should report as early as possible, and from the 5th to the 8th instant carefully examined the coast from Garrison Point on the west to East End Station, eastward, and was furnished by the Commanding Royal Engineer officer (Colonel Montagu) with every information and assistance I could desire.

The prevalent motion of the shingle on this line of coast is from the eastward, the result of which is a very large accumulation, forming a spit on the eastern side of the entrance to the Medway called Garrison Point. This has gone on increasing, as evidenced on the ground by the fact that the glacis of the eastern bastion is now rendered needless as a sea defence from the large accumulation of shingle in front or to seaward of it, and the same remark applies to the glacis round the works at Garrison Point. It appears, from the plans of Sheerness in your possession there, that in 1737 the end of the shingle spit was half a mile east of Garrison Point; and the same plan describes the then termination of the spit as 'growing beach,' and defines the amount that had then recently grown up from the eastward to the west-

¹ [Deal authorities subsequently exhibited notices, also Her Majesty's Board of Works.] •

² [This, in effect, is now the case, March 1862.]

³ [Not done. Consequences, retreat 100 feet of beach N. of Castle and flooding in December 1862 of marshes up to the railway.]

ward of this. The shore where now covered with shingle is described all the way to the Medway, as well as the foreshore seaward, as 'ooze.' Here, as the mass of shingle has increased, so has its size, and the usual characteristics of a sea beach, with two distinct 'fulls,' are presented.

The existence of an outer modern 'full' in advance of the old beach is also indicative of the increase of the Point, the western progression of which has amounted to from 2,800 to 3,000 feet in 120 years, viz., from 1737 to 1857, being at the rate of from 23 to 25 feet per annum. On the opposite shore, at Harwich harbour, a similar shingle-formation, called Landguard Point, has progressed in a S.W. direction at the rate of 50 feet per annum during the last twelve years.

Garrison Point appears to have been resorted to for many years for material for concrete for building purposes and for ballast for road-making in the Dockyard and for your Department. From the eastern bastion up to the turnstile a good foreshore of shingle continues, rendering unnecessary the old groynes, which have been allowed to go to decay. From the turnstile to the east end of your property, a frontage of nearly half a mile, are situate the works in question.

At the west end, *i.e.*, just east of the turnstile, from the degradation of the shingle, caused by the groynes being allowed to fall to decay, or from other causes, the sea has been allowed to impinge upon and breach a portion of the stone slope, which has only been partially repaired, and that at a very acute angle. The stone wall, with the exception of this breach, is generally uniform, but the original slope given to it, viz., from 2 to 3 horizontal to 1 vertical, is very steep; the toe or footing is protected by stake piles, which in places are getting undermined, and causing a corresponding settlement of the stone paving from the sea getting into the clay bed and washing it from beneath.

The shingle which is retained by the groynes running out from this wall is usually highest on the east side, showing the prevailing motion. The land ends are rather above the level of high water, and they extend in varying lengths and directions, generally about 120 feet in length, and with an average bearing N.E. by N. by compass; the wind to which the coast is most exposed blowing from the east by compass, and after gales from this quarter large quantities of cement stone pebbles are picked up along the beach, which work up out of the clay shore. The large quantities of oyster-shells on Garrison Point and the beach in front of the east bastion are also indicative of this movement.

The ends of the groynes mark the limit of the shingle, beyond which is a great extent of flat oozy foreland, amounting in breadth to a mile in places at low water of spring tides.

In front of the Royal Hotel is situate a groyne of greater extent, as to length and cross-section, than the others, through which the sewer from the hotel is carried, at the mouth of which, for its protection, is a curved horn. This groyne has promoted a deposit of ooze to the westward; and there is also a small accumulation of shingle, which is, however, entirely local, for westward of it the clay makes its appearance, with little beach to cover it, with the foot of the stone slope projecting above the foreshore.

The stone wall terminates by a rectangular return near the windmill, and there is then a deep recess up to the east end of your property; along this length of 114 yards the groynes have been allowed altogether to go to decay, the shingle has travelled landward, and the sea has gained very much on the shore, shown by the clay cropping out in serrated ridges through the thin beach, which only partially covers it. By a reference to Major Nugent's plan of October last the high-water mark appears coincident, or nearly so, with the shore ends of the groynes, but is now considerably landward of them, from this recession of the shingle. The degradation of the shore would also appear in the then proposition to lengthen these groynes, which are now quite decayed, and the piles of some of which may be lifted out of the shore, being only a few inches therein, showing a lowering of the foreshore on their site of about 3 feet. At the termination of your property at the east end of this bay or recess, and at the west end of Neptune Terrace, there is a very large old groyne of about six parallel rows of stake piles in steps to the westward, filled in with rough Kentish stone. This groyne has caused a local accumulation of shingle eastward of it, where the pebbles are from 4 to 5 feet higher than on the west side; but soon after passing this local accumulation we find the shore to the eastward very much denuded, the clay cropping through in ridges, a very thin medium of beach travelling landward. The shore appears to be lower to the extent of from 5 to 10 feet in places, as evidenced by the way in which it is dished out (leaving pools of water as the tide recedes)

between the land and sea ends of some half-dozen groynes, situate west of the jetty at Cheney House, which have been entirely abandoned and allowed to go to decay by the proprietors of land, who from their promiscuous cartage away of large quantities of beach and sand no doubt very much increase the evil.

Off the jetty is situate a local spit, Cheney Rocks, or, as it is sometimes called, 'China Rocks,' from the neighbourhood of which large quantities are likewise taken.

Eastward of the jetty, to the extent of the system of defence by groynes, the wall is paved on the face and defended by groynes very close together, being only from 10 to 20 yards apart, filled between with 'fulls' of fine shingle. The wall varies very much in direction with a recess just eastward of the jetty; it subsequently takes a direction more landward, is here more regular, and the beach has a better slope. At the eastern end the shore ends of the groynes are nearly level with the top of the wall as well as the beach. Eastward the groynes altogether cease, and we have a mole of shingle up to the preventive station, and thence eastward to the base of the clay cliffs of the island. Assuming two distinct 'fulls,' marking the respective range of springs and neap tides, it appears to have travelled landward a considerable distance during the last five years; it is said also to decrease in quantity. This recession of the shingle-belt has corresponded with the wasting of the clay cliffs of Minster, which is constantly going on, and evidenced at East End by a large amount of undercliff.

Between the shingle-belt at the coastguard station, or 'Ship on Shore' as it is locally called, and the Marsh Wall is a width of saltings, which in the winter time, during spring tides, and with the wind from the northward, is frequently overflowed by the sea, and may hereafter entail more attention on the part of the landowners to this line of wall.

From this general view of the shore, and a reference to the maps in your Department, there would appear to have been a gradual growing up of the shore westward, towards the Point, corresponding with the wasting of the cliff eastward; that advantage has been taken of this to reclaim the slob lands by degrees, some of the walls being in advance of others, and for the protection of these walls of earth the attempt has subsequently been made to secure a permanent protection by arresting the shifting beach by groynes; that this beach to the westward has grown out in advance of, and rendered superfluous, the groynes, and that in places to the eastward it has travelled landward of the groynes, and at intermediate points, from neglecting to keep up the groynes or to arrest the beach in travelling landward, and also from the irregular projections consequent on the want of concerted action, and from promiscuous and ill-judged removal of sand and shingle for building purposes, isolated lengths have suffered very much.

Were my instructions to report what I considered to be the best means of defending this line of coast, I should be disposed to recommend the construction of a sea-wall, or rather the extension of the stone slopes, and the abandonment of any other sea defences in the shape of groynes. This, however, would involve a much larger outlay than is contemplated in the Estimates for the current year, besides which my instructions direct my attention to the question of the best direction for the proposed new groynes. Neither has the cost for maintaining this wall been extravagant, for I find from returns furnished me at Sheerness that the cost from 1822 inclusive to the present time, including the estimated amount for the current year, amounts to 9,324*l.*, which is at the rate of about 267*l.* per annum for thirty-six years.

With the exception of the proposed expenditure this season, that of 1825 appears to have been the heaviest, reaching 1,300*l.*, mainly caused by damage from a high tide, arising in all probability from the upper works being out of repair.

The expenditure for terms of five years appears to be as follows, viz. :—

1822-25	£658 per annum.
1826-33. (No return. If aught were expended it would raise the rate of annual expenditure accordingly.)	
1834-38	£332 per annum.
1839-41	£111 "
1844-48	£220 "
1850-54	£92 "
1850-57	£159 "

The present is therefore apparently an exceptional and reconstructive year.

In construction, all the groynes along this coast are on a uniform local plan, consisting of two parallel rows of small round oak piles driven down about half

their length through the sand and shingle into the clay battering on the outside, their heads inclining inwards towards each other and nearly meeting, the intervening space being filled with rough Kentish ragstone; the piles in the longitudinal direction of the groyne are driven close together. Similar piling is used for protecting the margins of the stone slopes.

Where longer and loftier groynes than usual have been erected for the protection of projecting points, such as the west end of Neptune Terrace, or for a particular purpose, like the hotel-groyne, outer steps have been formed by rows of smaller piles, driven sloping and parallel with the inner piles, and filled in with stone, forming an outer ledge, sometimes constructed to windward, sometimes to leeward, and in the case of the hotel-groyne on both sides. The large groyne at the east end of your property has six parallel rows to leeward; the single and ordinary construction of groyne is generally from 2 to 3 feet above the shore, which is usually 12 inches higher on the east side than on the west. The short groynes have a fall of from 7 to 1 to 10 to 1, *i.e.*, taking the slope of the beach, the larger groynes are at their outer ends correspondingly more easy in inclination, being as much as 30 to 1, and even more corresponding with that of the foreshore.

There are some cases where, from this recession of the shingle, or from the peculiarity of position, like the groyne at the end of Neptune Terrace, the groynes are much higher above the shore. The above, however, is the medium where the wall, shingle-slope, and groynes are in good order; in other cases, as at the east end of these defences, where the shingle has accumulated, the groynes are not much above its surface. The prevailing mode appears to have been to run them out at right angles, or nearly so, to the length of wall they appertain to, and consequently presenting varying angles to the prevailing wind, with spaces or bays between of from one-half to one-fourth their respective length of groyne. In some cases the ends of the groynes have been connected together, with the object of retaining the shingle on the recoil; and in other cases triangles have been formed within the bays by two inner and shorter groynes running out at an acute angle from the roots of the main groynes, and meeting and forming an apex seaward, apparently with the same purpose—*viz.*, to retain the shingle on the return wave. This may be seen at Cheney Point, where, however, these artificial works are so close together—in one case two groynes cross each other at an angle that it becomes almost an artificial slope.

In the two plans proposed for the repairs and extension of your groynes the principles of construction hitherto followed have been adopted, and differ only as to the number, extent, position, and direction of the groynes. The aggregate length of work in each case, and consequent cost, are nearly the same.

The plan proposed by Major Nugent last October recommended the elongation, in certain instances, of existing sound groynes, and the introduction of new intermediate groynes, this view, no doubt, being encouraged by the favourable state of the beach at the eastern end beyond Cheney Point.

In this plan the groynes are nearly parallel to each other, from the east end to the hotel-groyne, and at right angles nearly to the mean line of high water. Those opposite the recess, between Neptune Terrace and the return end of the stone wall near the windmill, are about 53 feet apart on an average, giving bays of about one third the mean projection of the groynes; thence to the hotel-groyne the bays average from 32 to 33 feet in width, or from one fourth to one fifth the projections. Under the lee of the hotel groyne four groynes were proposed to be placed in a radiating position from a common centre, about 90 feet north-east of the outer end of the hotel-groyne, the bays between these groynes having a mean width of 45 feet, or about half the mean length of these radiating groynes, the western one of which would be detached from the shore at a very acute angle in a north-easterly direction. From this point westward to just past the path to Blue Town the groynes are proposed to be placed parallel to the old ones, *i.e.*, at right angles nearly to high-water mark, and to the mean direction of the shingle 'full,' dividing the shore in that extent into No. 15 bays, with a mean width of 37 feet each, equal to one third of length of groynes.

In the plan for the current year, by Colonel Montagu, the length between the road to Blue Town and the east return of the stone wall at the mill is alone considered. The groynes proposed are longer, and the bays wider, than in last year's plan. In order to retain the shingle after it has passed to the westward, the direction given to the new groynes is in two cases more westerly, with an obtuse angle to windward and an acute one to leeward. In a third case, the second from the west end, this direction is reversed; and to aid in promoting deposit, another principle, which has before been adopted on this shore (though not to the same extent), is here called in aid, *viz.*, to

have sea kants more inclined to the westward, but at varying angles; the present groynes are to be strengthened and extended by similar sea kants pointing upwards, with two exceptions, where they point downwards. This form has been adopted with the present hotel-groyne; in effect Colonel Montagu's bays would be much wider than those of his predecessor, but the openings to seaward would be covered or enclosed in a measure by the sea kants. Two new groynes are proposed east of the road to Blue Town and kants to the three existing groynes west of the hotel-groyne, a new groyne between the sixth and seventh groyne west of the N.E. return at the mill and No. 7 kants or elongations along the eastern frontage generally. The absolute length of new groyne work would be less than one-half that proposed in the first plan, but as some of these are treble groynes with two windward ledges, equal in extent of work to rather more than two ordinary groynes, and as a certain portion have one windward ledge, equal to rather more than one and a half common groyne, the absolute length of groyne work, *i.e.*, piling and stonework, will be nearly doubled; so that, considering the larger piles entailed, there would be no great saving in the amount as compared with the plan of last year.

This plan abandons the defence of the east recess, but the first plan would not now meet the requirements of that length without (to carry out its principle of continuous groynes) the addition of six new groynes in lieu of the old ones, which have continued to go to decay, and which are now too far seaward of the shingle to be of service.

I beg now to report, after a careful examination of the shore, and consideration of these plans, that I recommend the erection of three new groynes west of the hotel-groyne, *viz.*, one opposite the end of the road to Blue Town and two others east of this, with intervening spaces or bays of about 125 feet up to the present third groyne west of the hotel-groyne; that these groynes should each be 150 feet in length; that for two-thirds their length—*viz.*, 100 feet—they should bear N.E. by compass, which would be at right angles to the general trend of the shingle at high water between Cheney Point east and Garrison Point west, but presenting a slightly obtuse angle windward—*viz.* 98° —to the immediate length of wall they would front; that the extremities for 50 feet in length should be 45° more westerly in direction, or due north by compass, forming a sea kant; not that I think these kants collect or retain the shingle, but that they assist very materially in raising the foreshore by promoting a deposition of sand and defending the bays under their lee; that the main length of groynes for the straight portion should be laid at a slope of about 10 horizontal to 1 vertical, the south ends or commencements at the top level with high water, spring tides, and that the sea kants should be laid at double the above inclination—*viz.* 20 to 1—kept not more than 18 inches above the foreshore, and the main groyne not more than 3 feet above the mean level of the neighbouring shore; if the above inclination cannot be readily got, one of from 7 to 10 to 1 may give that elevation; that these groynes for the centre 50 feet should be formed of four rows of piles and three widths of stone, the eastern ledge thus formed to be 1 foot below the summit of centre width, and the inner or western ledge 2 feet below the same, and that the sea kant should have one outer or N.E. ledge 9 inches from the summit of said kant; that the existing groynes should be repaired where necessary; that the third groyne west of the hotel-groyne should be lengthened to 100 feet, and that its seaward half should be strengthened by a windward ledge, and where the shore is low (but not otherwise) a leeward ledge also, and that it should have a sea kant of 50 feet added to it, constructed the same as those of the new groynes; that the second groyne west of the hotel-groyne should be treated in the same manner; that the first groyne westward of the hotel-groyne should be left as at present with any necessary repairs; that the first groyne east of the hotel-groyne should be lengthened to the mean length of the three eastward in a N.E. direction, with a windward ledge; that the three groynes eastward should be merely repaired and strengthened as before; and that the next groyne eastward and each alternate groyne subsequently should have sea kants bearing north—*viz.* the third, fifth, seventh, and ninth groynes from the eastern groyne at the return in the wall.

The breach in the stone wall commencing about 40 feet east of the road to Blue Town, and extending about 100 yards eastward, should be made good; and I recommend that, as so great a length has been breached, a much easier slope—say double that of the present wall—should be adopted, in order to try its effect on this length; it might be rounded off to meet the present work at the sides, the sea margin to be carried well down under the foreshore and finished with a deep trench and footing of large stones, the large stones being selected for the lower part of the

slope for two-thirds of its width, and the widening of the bank to be done with well-punned clay in thin courses.

In other bays, where the margin of the slope has become undermined, it should receive immediate attention; and in such cases I should recommend the extension of the slope seaward at an easier inclination, to be carried well under the foreshore, with a footing as before described.

In front of the east recess I recommend the construction of one groyne precisely similar in direction and construction to those just described, about 115 feet east of the east return in wall, or one third the frontage of the recess eastward of the east groyne. A good deal of the waste on this portion of the frontage—which, however, can only be regarded as local—has been caused by the great height of the groyne at the end of Neptune Terrace. The effect of the groyne I propose may induce an increase of shingle, but my opinion is that ultimately it will be necessary in future seasons to take further steps for the protection of the east end of your frontage; and I consider that a stone slope immediately behind the shingle, to prevent its retreat further inland from the angle of the present stone slope to the end of the groyne at Neptune Terrace, would be the best remedy.

Before concluding, I beg especially to draw attention to the general condition of this shore, and beg to repeat the remark I made in a recent case where I had the honour of reporting to your Board, that this is to a great extent a landowners' question, and that there are practices going on all along the shore of the most suicidal character, and in some cases quite stultifying the measures taken for defence, arising from each owner merely looking to his individual interest and to the limited frontage under his control, accounting, perhaps, for the irregularity of the walls and varying directions of the groynes. The quarrying of cement-stone on the opposite Essex shore has been loudly complained of in reference to Harwich harbour. The mode in which it is taken from this shore at low water, over the enormous extent then exposed, can hardly be complained of; but the indiscriminate cartage away of shingle and sand from the spit running out at Cheney Point at low water, and along the shore to the westward, cannot be too soon put a stop to; but whilst it is the custom of your Department to remove material from Garrison Point it may be difficult to prevent others to the eastward removing similar material from their frontages. No doubt the removal of shingle from Garrison Point produces less harm, and it has arrived at a point from whence it is desirable it should not extend itself to the westward. I do not, however, think that the manner in which this spit extends itself—similar to other like formations—threatens the Dockyard, for it is increased seaward by parallel ridges or 'fulls,' which would, as they increased, extend themselves eastward, and any abstraction at the western end must, if that view be correct, be a loss eastward.

On the other hand, what is abstracted eastward cannot pass westward, and robs that quarter; so far, it is a relative question of quantity. The two cases are, however, really very different. I understand that the shingle has usually been taken from Garrison Point, where it is highest, largest, and in greatest mass, and consequently least missed; but at Cheney Point, whilst I was there, carts went down at low water and removed material from the shore, where it was most wanted for protection. Great mischief is, no doubt, being done, and this indiscriminate and injudicious mode of removing this material for immediate gain appears to me most hurtful to all interested in the neighbouring foreshores, and even to the prospective advantage of the owner, who, however, if this be a public injury, can, I take it, be stopped in these operations through the Woods and Forests Department. And I may in illustration refer to a recent case at the mouth of the Humber, where, by the indiscriminate removal of pebbles from the Spurn Point, for ballast and other purposes, a breach has ensued, which has resulted in a very heavy expenditure in works, which might have been avoided had attention been drawn to the matter earlier. This particular case attracted considerable attention in the House of Commons in a recent Supply debate.

I feel that, viewing the mere letter of my instructions, this may appear a very lengthy report; but I felt it impossible to give any opinion on the particular subject referred to me without reporting on all the attendant circumstances that must so materially affect an inquiry like this.

Having had surveys of the foreshore placed in my hands, which I verified, to a certain extent, by taking bearings on the ground, as also cross-sections of the beach, I did not consider it necessary to prepare any additional plan, but have merely appended some marginal sketches, which, with a reference to the plan of July 18,

1857, by Colonel Montagu, which I herewith return, together with Major Nugent's plan of October 29, 1856, will be, I think, sufficiently illustrative of my meaning.

I am, Sir,

Your obedient Servant,

(Signed) J. B. REDMAN.

3. EASTBOURNE CIRCULAR REDOUBT SEA-DEFENCES.

To Lieut.-Colonel Owen, R.E.

5 New Palace Yard, Westminster, S.W., December 24, 1857.

SIR,—On the 25th ultimo I was favoured at the War Office with your instructions to report after inspection, for the information of the Secretary of State for War, what, in my opinion, would be the best course to pursue in repairing the damage done to the breakwater at the Circular Redoubt by the gale of October 7 last, and for the future maintenance of this work.

For this purpose I went down to Eastbourne the evening of the 1st instant, and had the opportunity of inspecting these works during the low spring tides of the 2nd and 3rd and the morning of the 4th inst., as well as seeing the effect of the sea upon them, as there was a fresh breeze from the southward and westward, with a heavy sea at high water during the whole time of my visit.

Captain Baillie, who met me on the work on my first inspection and on other occasions, afforded me every information I could desire.

The length of coast under consideration consequent on the projection of Beachy Head bears N.E. and S.W., but I have thought it more convenient to speak generally of the points under consideration as being east or west of each other in reference to the general direction of the south coast unless otherwise specified.

It is hardly necessary for me to dwell at any length on the various evidences there are to show that the sea has continued to encroach for some years past from Beachy Head westward to Langley Point eastward, or how it has resulted from this that the defences at the Circular Redoubt form themselves into a projecting point as the shore has receded east and west of it; very similar in effect to Sandown Castle, on which I had recently the honour of reporting to your Department, all this being clearly shown in Captain Baillie's surveys, with copies of which I was furnished and had with me to aid me in this inquiry.

To the westward, along the frontage of the 'Sea-Houses' at Eastbourne, it has been for some years a contest with the elements, the source of constant outlay, and, from the state in which the foundations of the sea wall are now in, exposed as they have been at low water by the withdrawal of shingle produced by the late easterly gales, this outlay is likely to be very much on the increase, without a re-accumulation of shingle quickly takes place.

In the bay, between the esplanade and the Circular Redoubt, the recession of the shingle is evidenced by the proposed abandonment of the present coastguard station. Immediately west of the Redoubt there is a tolerable 'full' of beach, which, however, has travelled landward, as evidenced by the hardness of the lower slope and thinness of the shingle and amount of sand, and also by the abrasion of the old glacis slope, some of the turf from the serrated edges of which I found lying on the beach below during my first inspections. Nor has the west timber revetment been extended far enough to the westward effectually to guard against this.

On the east side, the recession has been checked by a concrete revetment wall, which appears to have answered the purpose, having been erected half a dozen years back, and the shingle is still seaward of it.

The effect of this land recession is—the continuity of the shingle mole is destroyed, the artificial works for the defence of the Redoubt cutting through it, and there is consequently deeper water immediately in front of them east and west, rendering the collection of shingle in front by groynes more and more difficult, as well as the maintenance of any artificial works, from the increased depth of water.

It appears, from plans belonging to your Department at Eastbourne, that in 1805 the sea at high water was 120 feet seaward of the inside line of the counterscarp-wall, or 250 feet from the centre of the redoubt. In 1808 these dimensions were relatively 90 feet and 223 feet, showing a wasting of the shore of from 27 to 30 feet in three years, equal to from 9 to 10 feet per annum. Referring this comparison to Captain Baillie's survey on the east side of the redoubt the difference would be 238 feet in 49 years, equal to one-half the former degradation, viz., $4\frac{1}{2}$ feet per

annum. On the west side it would be still less, viz., one-third the amount that it is on the east side, viz., $1\frac{1}{2}$ foot per annum. It would thus appear that the recession of the shore line was greater over former terms of years, or that the artificial works at this particular frontage have kept it in check. The effect of the Redoubt and its works is, like that of a groyne, to keep up the shore westward. Were these works abandoned the shore west would recede accordingly.

Surveys by the same authority (Searle) in 1808 show the degradation of the shore as far as Langley Point.

No. 72, Martello Tower, the one adjoining the Circular Redoubt, was removed some years since, consequent upon the encroachments of the sea. No. 71 has apparently been underpinned with stone, and is also protected by a groyne to the leeward as regards the prevailing westerly winds, viz., to the east, which has promoted an extension of the shingle in that immediate neighbourhood. In 1808 high-water mark was 175 feet from the centre of No. 70. It is now 35 feet from it, equal to 140 feet recession, or nearly 3 feet per annum. No. 69 was 195 feet, and is now 50 feet, giving the same amount of degradation; and the old fort between these towers, which was dismantled some sixteen years since, had 50 feet of beach seaward of the most salient angle at high water-mark, which latter is now in a line with its centre, or 140 feet back as before. The degradation of the shore west of the point is also shown by the exposure of about 3 feet of brickwork below the mastic with which these towers were coated two years back.

No. 67, on the other side of the Point, had 170 feet, and has now nearly the same, showing that the degradation is confined to Eastbourne Bay, and ceases on the west side of Pevensey Bay. The east fort had 85 feet on the outside, and has now nearly the same.

No. 66 had 170 feet, and has now 200 feet, showing that there is a local accumulation northward of the point, but this appears to cease to the eastward.

No. 65 had 108 feet, it has now the same; and Nos. 59 and 60 had 150 feet in 1810, and now have much the same.

These facts are sufficient evidence of the continued abrasion of the west shore of Langley Point, which at a former period extended much further westward, as also a much greater distance into the sea. This has had a corresponding effect along the frontage of Eastbourne Bay, but I do not think, on comparing the results with those obtained some ten years since for another purpose, that there is any evidence that the encroachment has been materially on the increase in the neighbourhood of the Redoubt of late years, but, on the contrary, that its rate has rather diminished or been held in check as along the frontage of the town by works of art.

The present low state of the shore in front of the Redoubt appears to be due to the late easterly gales and consequent withdrawal of the shingle. As the latter can, however, only be regarded as a fluctuating medium of defence, it will be well to take the level of the shore as I found it as a datum for laying out any future works. The two west bays I found lower than usual, and Captain Baillie informed me he had never seen them so low as during my visit, and the breastwork was consequently more exposed than when he made his report. I found the west timber revetment at the west end and at the ninth groyne 2 feet above the shingle, at the centre of revetment 6 feet above, and at its east end 5 feet 6 inches above; the south-west angle of the bulwark 3 feet above; the bulwark at the eighth groyne near the west end 5 feet above, at the seventh groyne 6 feet 5 inches above, at the angle at sixth groyne 9 feet 3 inches above, at next angle 8 feet 3 inches, at angle west of fifth groyne 5 feet 6 inches above, and east of fifth groyne 5 feet 3 inches; thence running up eastward to level of bulwark, where it continued to gather during the latter part of my stay, until it stopped and ran over the south-east angle of the bulwark into the next bay.

It appears that usually the west bay revetment and west end of bulwark have a bed of shingle in front, which was, during my inspection, as will be seen above, very low, but was again accumulating. The recent abrasion on the east side is shown by the east groyne being visible, as it is usually buried in shingle. No. 2 groyne is also usually more covered. No. 4 groyne appears usually to have a good supply on each side, but the great accumulation appears usually to cease at the angle here. Captain Baillie proposes a new groyne, but even here it appears that the face of the breastwork is not usually exposed. The most exposed point, as might be expected, is the salient angle at groynes Nos. 6 and 7.

The shore fronting the redoubt may be said to be divided into eight bays by No. 9 groynes, throwing out of consideration the more ancient and dilapidated ones.

East of the artificial works the shore, as before described, and as may be seen by referring to Captain Baillie's survey, recedes suddenly and the crest rises, as in other similar situations, being higher than any accumulation at the Redoubt, as at Sandown and elsewhere. East of No. 1 groyne there are 10 naked piles, the remains, apparently, of an old groyne, exposed by the withdrawal of beach caused by the late easterly gales.

No. 1 groyne is lower than those to the west. It points in a S.S.E. direction, and is well backed up with beach, extending to within a few yards of the end of it.

No. 2 groyne is constructed with an offset, or kant. The landward length bears S. 7° E., and the seaward length S. 5° E. The inclination of this groyne is good, and it has a compact mass of shingle well up to it within 18 inches of the top, extending about 30 feet beyond the kant. Eastward the shingle recedes, and is only just beyond the kant.

No. 3 is an old dilapidated groyne running transversely across the bay between the two kanted groynes (Nos. 2 and 4) in a direction S.S.E., $2\frac{1}{2}^{\circ}$ S. The shore between this and the new groyne (No. 4) was 6 to 7 feet below the latter, which is also constructed with an inclined offset or kant like No. 2, the land length bearing S. 8° E., and the sea length S. 9° E. The effect of this groyne has been to form a local accumulation of shingle, heaped up from 4 feet to 6 feet higher than to leeward, but quickly declining to the westward, as before described, running over the S.E. angle of the bulwark, whilst the return of the latter was 5 feet above the shore to leeward, the margin of the shingle extending to within 30 feet of the kant.

To the eastward of No. 5 groyne the shingle was 5 feet below the bulwark, whilst in the same bay in so short a distance it was running over the top of it at the east side. This groyne bears S.S.E. $1\frac{1}{2}^{\circ}$ S., and had a tolerable 'full' against it 3 feet higher to windward than leeward, but decreasing very much in breadth seaward, the bay east of it being low and bare, composed of fine shingle and sand; the beach in this bay, the widest of all, immediately west of the breach narrows and draws in suddenly with a curve, due to the projection of the breakwater. There are the remains of two old groynes west of No. 5, which I have not numbered, the piles of which are subsequently found running up through the breached work of the breakwater. The stumps of three ancient groynes may also be seen on the foreshore towards low water about the centre of this bay, and similar remains may be traced at top through the beach near the breakwater, standing evidence of the encroachment of the sea.

No. 6 groyne is much decayed. It bears S.S.E. $2\frac{1}{2}^{\circ}$ S. There is a fair amount of shingle against it, but not extending far out seaward. No. 7, which is in better order, extends in a S.S.E. direction, and had beach apparently increasing during my visit about 2 feet higher to windward than leeward.

No. 8 groyne was much ruined; also in a S.S.E. direction. The beach was evidently gathering here again on the morning of the 4th inst., as the west timber revetment and west end of breakwater were then only from 18 inches to 4 feet above the shore, and there was a good supply of shingle in the west bay, and it appeared to be again growing up west of the west groyne No. 9, which bears S.S.E. $2\frac{1}{2}^{\circ}$ S., but which is much out of order, particularly at the end.

The effect of these groynes is, as elsewhere, to cause an accumulation of shingle to windward, as regards the prevailing wind, with a corresponding depression leeward, the shingle sloping down to the west. This is shown in a remarkable degree at the new groyne No. 4, on a line with the east margin of the breakwater, where the beach was 7 feet higher, during my visit, to windward than to leeward; and the two north-east groynes beyond this are much lower than the new groyne.

It would be well to keep up the existing groynes at the landward ends near the breastwork, where they, no doubt, promote a retention of the shingle, but I am not inclined to recommend a great expenditure in extending this system. The site pointed out by Captain Baillie is, no doubt, a good one, if a new groyne be erected; but in that event a length equal to one half that of the new north groyne would, I think, be sufficient. The effect, when the continuity of the natural mole of shingle is destroyed by its own recession and the consequent protrusion of a work of this kind, is that no more than the lower 'full' can be retained, and the beach travels onwards and landward, irrespective of the groynes.

A pier erected northward and eastward of these defences might arrest a large quantity of beach, but would be nearly as costly as maintaining the breakwater, and the works to leeward towards Langley Point might suffer correspondingly. With the problematical results that may be anticipated from any extension of the system of groyning, I am disposed to recommend the maintenance of the breakwater.

I have directed my attention to three modes of protecting this work, viz., by an extension of the system of groynes, the abandonment of the present breakwater, and the construction of an inner sea wall nearer the redoubt, intersecting the counter-scarp wall, and the strengthening and maintaining and extending the present sea face, and am induced to recommend the latter course.

There are, however, it appears to me, serious defects of construction in the present breakwater, and I will first describe the state in which I found it, and what appear to me to be the causes of its failure. These my inspections will enable me to do, as the western or southern half remains entire, and the eastern or northern half has been breached over almost its entire surface, exposing to view the débris of former defences, on which the present have been founded.

The glacis of the redoubt appears formerly to have been formed of shingle and earth coated with clay and grass-grown. As this became abraded by the sea, consequent on the recession of the shingle, a system of defence was adopted known along the coast as 'arming,' faggots being driven down over the surface of the slopes, holding down watlings by means of overlaths. Many of these old and decayed faggots may be seen at the present time in the breach, and this is one of the defects of this work—that succeeding defences have been added and placed above the old ones without removing them or obtaining a sufficiently solid base. As these old works have decayed they have subsided and left vacuities under the modern works. This remark applies to the timber wharfing or bulwark of the apron or breakwater erected so recently as the summer of 1856, formed of whole timber piles 22 feet long, which are now, in places, exposed nearly half their length, driven 4 feet apart alternately in front and to the rear of 4-inch horizontal planking, backed with 4 feet of block concrete, the outer piles being held back to land-tie piles only 4 feet back in the rear of the concrete; and it appears that behind all there is an old timber breastwork. The angular space between the old slope, the outer breastwork, and the surface of the present slope is formed of shingle covered with concrete, which receives the stone paving or brickwork, as it may be. Through this shingle substratum the sea must percolate freely. This is seen now at low water by the great quantity of water running out through the bulwark and gulling out a small run of water across the shore just east of No. 5 groyne, which has previously been penned up after high water in the breached portion. When the general character of the work is considered, the constant infiltration of the sea has been one of the causes operating in producing settlement, in addition to the decay and subsidence of the materials of former works; added to this, the timber breastwork, when exposed to the impact of the sea towards high water by the removal of shingle usually lying against it (which is its present condition, consequent on the late easterly gales), is not of a nature to resist effectually the enormous force brought to bear immediately against it, which, during my visit, caused a sensible vibration through the whole mass of the breakwater, and threw up a column of water about 30 feet high. Where the bulwark projects above the shore, an overfall is created on the receding of the wave, tending to scoop out the shingle. This applies to the east and west ends. Where the shingle is level with the top at the south-east end the sea runs over without breaking. The brickwork forming portions of the slope laid in the summer of 1856 is much worn from the abrasion caused by the shingle dashed against it at high water, and the concrete slope above appears very doubtful, having apparently swelled upwards in places, and sounds quite hollow to the tread. The manner in which the breastwork springs or yields back and then forwards, consequent on the removal of the shingle in front of it, by which the weight of the material of the glacis is brought to bear against it, has been well described in Captain Baillie's report. This produces a loosening of the stones of the slope at the joints, which are subsequently readily removed by the sea. During my visit, by the settlement outwards of the breastwork, the main longitudinal joint between the marginal stones and pitching required pointing, as also some of the main longitudinal joints up the slope; and along the south-west frontage the coping stones had settled vertically, leaving the brick projecting, and which may thus be readily undermined.

Where exposed, the breastwork is being strengthened at the most projecting angles seaward by open piled and braced counterforts, to counteract the tendency it appears to have to settle outwards consequent on the removal of the shingle. The same thing has taken place with the old south timber revetment, which has settled outwards, and is much out of line with an intervening space between it and the concrete backing. It is possible that the free admission of water into the foundation of this work, the paving having close joints, with a homogeneous body below for a

certain depth forming the surface of the slope, has been one cause of its failure, as has been the case in other works where a paved surface not admitting the passage of the sea has been placed on a substratum which does. The result is, a hydrostatic pressure is evolved by the difference of height of the wave outside compared with the level of the water inside, which is comparatively at rest, tending to raise the impermeable work forming the surface of the glacis, which, aiding the wave on the recoil, may be one of the destructive agents at work. In the present case this is to a great extent conjectural, and I am more inclined to think that the settlement of the breastwork and inner work, and the consequent loosening of the surface work receiving the direct impact of the sea, are the more immediate causes of its failure.

The best mode of protecting the Redoubt effectually is the next question, and is, no doubt, a difficult one. The foreland along this shore is not of great extent, and from the way in which it has been deepened in front of the Redoubt, the tide, when once it makes, is soon over its surface, and would quickly gain on any outer works, increasing the difficulty and first cost of construction as well as that of future maintenance.

There are two modes by which the sea defences might be extended: first, by continuing the slope from the top of the bulwark down to the foreshore; and, secondly, by an entire reconstruction; the latter of which courses I beg to recommend, as the present height of the bulwark is so great that to carry out a sea slope from that level would entail a much larger surface and mass of work, and would bring it so near low water as to render it almost impracticable, or else a very steep slope would be required. In carrying out this work it would not be necessary to remove entirely the bulwark, but to pave up to it and to cut off so much of the piles as interfered with the level of the proposed slope. The work seaward of its present extent should be formed of much heavier blocks than those now used, laid dry upon a foundation of broken stone or shingle mixed with tempered clay above; where less influenced by the tide, on concrete. The main groynes should be repaired at their landward ends, as they would form convenient bays for getting in the work, as well as limit the area of damage should breaches hereafter occur.

The sea margin of the elongation of the slope should be formed of still larger stones, stepped down in a trench and founded as before described. To render the sea slope more secure, I propose, in addition, that there should be longitudinal and transverse crosses or walls, as shown in the drawing. These should be founded on work in trenches, as described for the toe or sea margin of the slope. They would have the effect of limiting the area of future breaches. The upper portion of the slope might be continued, as occasion required, to the profile shown in the accompanying section.

In doing this, the remains of old work should be first removed, and I am of opinion that the sea should be allowed to give its own slope to the débris over the breached portion, and that it should be left to settle during the winter, and if the breach extends itself westward such further exposed portions should be treated in the same manner, the interstices to be filled in with broken stone and materials from the old slope, and all old timber and faggots removed; the slope to be then gradually brought up, composed of well-tempered clay, mixed with shingle and broken stone. Shingle itself without such admixture appears to me a most unfit material, from its character, to form the base of such a work of, for, unless in equilibrium or closely confined, it will settle down and run out like water through any outlet formed by a breach or otherwise. The existing groynes should be repaired near the bulwark as far out seaward and as high as the beach usually collects. Any greater extension or elevation appears to me useless.

A small groyne where proposed by Captain Baillie would, in all probability, prove a useful auxiliary, say 90 feet long; but instead of placing the entire length obliquely across the bay, as suggested by Captain Baillie, I propose that for two-thirds its length, viz., 60 feet, it should point S.S.E., and the remaining third, viz., 30 feet, S.S.W., as shown.

The extension of the breakwater beyond the present bulwark I estimate would cost 3,000*l.*; the work above, 2,000*l.*; making a total of 5,000*l.*

I return herewith Captain Baillie's plans and sections (No. 3 sheets). On two of them, descriptive of the Redoubt, I have marked in red the numbers and bearings of the groynes as I have distinguished them, and also the levels of the bulwark above the shore.

I have the honour to be, Sir,

Your very obedient Servant,

* (Signed)

J. B. REDMAN.

APPENDIX.

The gale of October 7, which caused the breach in the breakwater, commenced from S.S.E. and veered subsequently to S.S.W., from which quarter it continued the following day. During the rest of the month it blew alternately from the westward and eastward, slightly in excess from the former quarter; but during the month of November there was an unusual amount of easterly winds, and from the middle to the end of the month strong gales from that quarter were experienced.

Since my first inspection of these works the wind has been entirely from the west, the continuous east wind in November accounting for the extreme lowness of the beach during my survey, and the change of wind producing re-accumulation.

4. SANDOWN CASTLE.

To the Secretary of State for War.

5 New Palace Yard, Westminster, S.W., October 11, 1860.

SIR,—Your instructions of August 11 last directed me to report—

First, on the practicability of permanently maintaining the Castle even though it were entirely separated from the shore on either side of it.

Secondly, as to the mode I should propose to adopt for this object; and

Thirdly, as to the probable cost of such an undertaking.

With this view I visited the spot the morning of the 17th ultimo and repeated my inspections the three following days, and was certainly not prepared for the great change that has taken place since I reported four years back, in 1856. In that report I detailed at length the then condition of the shore, illustrated by an accompanying plan from Sandown Esplanade to Battery No. 1.

The beach has continued to retreat and gain on the shore, as this latter is washed away. North of the esplanade and between it and the windmill the edge of the bank that crops through the upper shingle 'full' is now considerably behind the line of the esplanade railings with which it was in a line in 1856. The foreshore northward is thinner, and although the South Castle groyne and timber revetment hold a certain quantity of shingle in check, which, however, was recently scoured away and has since re-accumulated, and is, indeed, as high at the south groyne as in 1856, the condition of the shore northward is altogether altered.

I may state generally that towards the western ends of the groynes the shore has lowered to the following extent: at the south intermediate groyne it is on an average 3 feet lower; at the centre groyne, the western end of which for 30 feet in length next the Castle has disappeared, the shore is 4 to 5 feet lower; at the north intermediate groyne 3 to 6 feet lower; and at the north groyne 8 feet to 13 feet lower. Indeed, this work had been left hanging up, as it were, at its landward end until upset by the fall of the north moat revetment counterscarp wall, the shore being washed away down to the very pile shoes, and the same remark applies to the north timber revetment, from behind which the shingle has been scoured out vertically for a depth of at least from 12 to 15 feet, leaving a clean section of sand-hill 12 feet in height fronting the sea, where formerly existed a shingle mole; and 16 feet in height of the old moat-wall is also exposed.

All the old 'fulls' of beach north of the north groyne are gone; they appear to have gradually decreased for the last three years, but a 'full' of beach level with the top of the north timber revetment, now entirely isolated, existed, it appears, six months past; the mark, indeed, may be seen on the adjoining moat wall, the shore is now 12 feet lower, and what shingle there is, is driven landward. Northward of this, towards Battery No. 1, the degradation of the shore has been almost as remarkable, and the sand 'dunes' now crop for continuous lengths through the shingle mole (which is now much thinner and further inland), and not in isolated patches as described in my report of 1856. The effect of this has been the almost entire destruction of the sea works of Battery No. 1.

The result of this remarkable lowering of the foreshore immediately under the Castle, consequent upon the disappearance of the mole of shingle northwards, has been the continued and increased exposure of the base of that work; and although various attempts have been made to underpin the footings, the main Castle-walls, from numerous appearances therein, appear to have received some amount of injury from the constant percolation of water under the foundations, and the withdrawal therefrom of the same on the recession of the tide causing the loose sand to be drawn away from below the hard crust of sand on which the edifice immediately rests, and

which, on exposure to air and water, by degrees assumes its original character, only showing more plainly the danger to which the structure has been subjected by this continued exposure.

The result of the great recession of the shore north of the Castle before described and delineated on the accompanying plan is that the sea eddies round the building, which at high water forms a kind of point or headland, and the sand is scoured out from under or before the Castle walls: this great decrease in the height of the foreshore has not only induced the permanent loss of beach from its not re-accumulating at a level so much below high water, but the sea also much sooner reaches the Castle walls, rendering the difficulty of construction of any permanent work of defence greater year by year. Another result of the lowering of the shore and loss of the shingle barrier is that the Castle walls are much sooner reached by the tide, longer subject to its influence, and that the footings are gradually more and more undermined, and the sand crust on which they rest exposed in the same degree, and that the body of sand below is more saturated, and a larger amount is withdrawn by the tidal recession. That the sand is highly charged with water under the Castle is shown by the manner in which it pours from under it over the foreshore at low water, and the manner in which it boiled up from under the footings in the trial holes that were sunk for their examination, when none was to be seen coming in from the opposite side. The result of this constant saturation beneath the foundations and withdrawal of water therefrom in such a material as that on which they are founded is evidenced by the numerous fissures in the outer main walls of the building, in the piers therein and in the basement gallery walls; still former fissures existed of considerable standing of which many of the modern ones are merely an extension. Similar indications of settlement may also be traced in the upper embrasures, though these latter may be attributable in a degree to the age of the building and causes producing vibration.

The settlement of the main building is shown by a fissure around the small window in the keep staircase turret; those in the basement walls may be traced all round, and appear worse next the sea. Some are older than others, and have been pointed up some time back. The more recent settlement is shown in places by the breaking of the Caen ashlar stones where the bearing is unequal. The vertical settlement is also shown by the bridge from the ramparts to the door into the principal room of the keep having altered its form; many of these indications are, however, of considerable standing: this may be remarked of the basement, especially on the land side.

There are fissures in the footings of the south revetment or counterscarp wall indicative of settlement and an outward movement similar to that causing the failure of the north wall.

The natural result of the withdrawal of so large a quantity of the sea barrier immediately from the base of the north moat revetment or counterscarp wall has been for the last six months to gradually undermine it from the seaward and to carry the sand away by degrees from under it by the underdraught of water from the moat on the recession of the sea. The wall, which had cracked in various places, fell over in three detached masses, leaving two large breaches for the sea to enter by on the 11th ultimo, just as the brick wall of Battery No. 1 had previously fallen from similar causes.

If the Castle is to be maintained something must be done immediately.

In the first place, I recommend the removal of every remaining timber of the north groyne, north intermediate, and centre groynes, and of the north timber revetment from its present site.

The south intermediate groyne, south groyne, and south timber revetment to be retained for the present, as their removal would entirely alter the condition of the shore southward.

In reference to the above remarks and those that follow, I beg to refer to the plan accompanying my report of 1856, also to the enlarged plan of the Castle and adjoining frontage, showing the proposed works accompanying this report.

I next recommend the immediate construction of a sea barrier across the moat from the outer or N.E. curve of the N.E. tower to the angle in the moat, retaining wall formed by the intersection of the two circular curves therein, such barrier having a N.W. and S.E. direction, and including within it the moat tank or drainage cesspool. It might be formed of the blocks of stone from the fallen north revetment wall, backed with masses of concrete therefrom, and the whole backed up with material procured from the neighbourhood, the pitching of the crest and back slope laid on clay puddle.

As a further precaution, I recommend at the same time the erection of a counter-dam across the opening under the drawbridge to the north of the basement gallery doorway, and near where a similar former work stood, this barrier to be continued along the base of the drawbridge pier or causeway as hereafter described.

The object of the outer dam would be to prevent the sea ranging into the moat as at present, threatening, as it does, to undermine the north side of the N.E. tower, where a height of 4 feet of the compressed or hard sand is now displayed below its exposed base. The north groyne of the drawbridge pier is in the same peril, caused by the indraught of the great body of water at high water of spring tides that there passes under the drawbridge through the narrow opening. The effect of the outer dam would be to arrest the travelling shingle and to cause it to form in front of it instead of being spread over the moat.

The inner or counter-dam under the drawbridge would confine the sea to the northward of it in the event of the failure or leakage of the outer barrier, and would prevent the damage to the south moat revetment or counterscarp wall, now likely to arise from so large a body of water getting behind it. The ill effect of this may now be seen by the quantity of water that pours out on the receding of the tide through the foreshore from under the Castle walls.

A paved watercourse should, I think, be constructed outside the outlet pipe through the south revetment-wall, the scour from which at present is promoting an undermining of the wall.

Coincident with these works I propose that the north timber revetment be retreated and reconstructed against the sand face now exposed by the undermining of the sea.

The broken edge of the north moat wall to be formed to a slope to approximate with that of the outer sea barrier in the moat, and the timber revetment when retreated and faced with stone to form a kind of projecting pier between the two.

The exposed portions of the N.E. tower base, consequent on the failure of the north revetment wall to be underpinned.

The heart of the sea-barrier, of the counterdam, and of the backing of the north revetment, to be formed with clay puddle, the two former to be also furnished with wooden trunks or sluices and self-acting tidal flaps of timber, say 1 foot 6 inches square, hanging outwards to allow of the retreat of any tidal water that might gather behind the same from leakage or the swell from high tides topping them.

A slope or bank of earth to be thrown up against the north side of the drawbridge pier or causeway in continuation of the counterdam and faced with stone. This portion of the work at present is very insecure, the stone ashlar in places being quite honeycombed behind into the backing.

If the Castle is to be maintained, the whole of the above works should, I consider, be immediately executed to make it at all habitable for the approaching winter.

Should the present *statu quo* continue, I apprehend the probable failure of the N.E. main tower and the almost certain fall of the drawbridge pier.

The whole of the above works can, however, as regards the permanent maintenance of the Castle, be only regarded as comparatively temporary in their nature.

Their cost I estimate at 800*l*.

Although I submit herewith a plan which I consider will achieve the object in view, I feel some hesitation in recommending its adoption without first explaining what appear to me inherent defects in the structure to be defended.

The work, looking to the date and character of the masonry, exceeding three centuries of age, composed of small materials, was built more as a landwork, when there was a considerable barrier betwixt it and the sea, than as one to withstand the attacks of the ocean, and was founded somewhat superficially on sand, which, from the stealthy encroachments of the sea, has been undermined by degrees—it is difficult to say to what extent. Not only is the work from these causes somewhat doubtful, but, viewing the continued effects of the sea in its present condition, it will become more so.

If it be determined to maintain it, I propose that hereafter the maintenance of the moat walls and revetments be abandoned, and that the main outer walls of the Castle be entirely surrounded by an enclosing basement wall, to be carried up 18 inches above the sills of the lower or basement embrasures, which would then probably require to be walled up solid, as those at present next the sea now are, or at least on the north and south sides; this level for the top of the enclosing wall would be the range of high spring tides; that this wall above be made nearly parallel to the inclined base of the Castle walls with more projecting courses below, giving it a curve outwards, the foundation carried down to within 4 or 5 feet of low water of

spring tides, that is, vertically 16 feet from its summit; that it be made from 4 feet to 10 feet thick of solid masonry, in large blocks pinned and cramped together as it progressed, and set in hydraulic cement, the largest blocks used in the base with off-set courses as shown in the drawing. Such a wall would be considerably below the present base of the enclosing outer walls of the Castle, which it might be made to underpin in places by having projecting corbelled courses carried under and wedged up to the same; it would have to be got in in short lengths, and the excavated face kept sufficiently in advance of the old walls to clear the hard sand crust in front of the same next the sea, and the excavated face below supported by piling, caulked if necessary, as the excavation progressed, to prevent any disturbance of the material below the present walls. The outside of the toe of such encircling wall to be enclosed by another parallel row of sheet piling driven down 12 feet below its base, *i.e.*, 4 feet below the level of low water. Each row of piles to be of rock elm timber, connected by longitudinal wales, and together transversely, as shown, the excavated trench within got out in short lengths and filled with clay puddle and concrete. The greatest care would be requisite not to disturb the ground under the Castle walls.

To avoid this it is, as before stated, proposed to keep the encircling wall at its base, say, 5 feet from the present footings, and pile it at the base on both sides, as shown on the accompanying plan.

The above plan appears to me to present the fewest possible objections out of several that have presented themselves and been considered. To underpin thoroughly the existing walls would be exceedingly costly and difficult, and the driving of piles near them hazardous. By keeping the inner work in advance as above proposed this objection would be obviated, the pile-joints might be caulked, and the areas limited by temporary cross-piling.

This plan would, next the sea, admit hereafter of extension or widening at the base should the shore lower still further, by the addition of another outer row of piling, and stepping down the foundation within the trench so formed, as shown by the dotted lines in the sections.

Or this lowering of the shore might be met by a more economical plan, *viz.*, stone paving on concrete and clay, forming an apron next the sea, as proposed in my report of 1856.

In addition to the main enclosing basement wall, I propose that the moat walls should, on the west or land side, be removed to the level of the sills of the lower embrasures, the chalk hearting therefrom, and the material of the sloped embankment to be used in filling up the moat between the N.W. and S.W. towers, as shown on the plan, maintaining the south revetment walls and the south timber revetment as long as possible, for the reasons before stated, leaving sufficient of the old moat wall standing to form a pier to the drawbridge and a portion of the bank to form an approach to the same, the masonry from the moat walls to be used as a pavement over the surface of the moat so filled in on a bed of clay puddle; the effect of this would be to confine the range of the sea behind the Castle, at present undermining the work on the N. side, where there is now 3 to 4 feet of water at high water of springs, and it would render the basement drier if the above were done; from one-third to one-fourth of the circumference of the proposed main wall of defence might be dispensed with until the sea had made further inroads: this on the assumption that the N. moat barrier and N. timber retreated revetment are maintained, and the shingle forms in front of them; should they not be, the shingle would continue to retreat, and the main enclosing wall must then be made continuous, and any further attempts to maintain the south revetment wall abandoned.

The total cost of the permanent works for the isolated defence of the Castle I estimate at 16,000*l*. If the west side of the enclosing wall be dispensed with and the moat filled I estimate their cost at 12,000*l*. They might be postponed until next summer and until the effect of the more temporary measures first suggested are demonstrated; the immediate execution of these last I consider absolutely necessary for the safety of the Castle.

In order to ascertain that no material change had taken place since my first inspection of the 17th ultimo I again visited the Castle on the 8th instant.

I found that 95 feet of the west portion of the north groyne had been carried away by the sea, and that a further portion of the adjoining counterscarp wall had fallen, and the main fallen masses of the north revetment or counterscarp wall on the east or sea side leaned more over seaward, and that the fissures under the south revetment wall were more open.

I also found the chalk-rubble bottom of the moat behind the breach more gulled

into by the sea, with sand forming over the same, and a beach 'full' thrown up as delineated on the accompanying plan, the crest of which was 18 inches below the sill of the first embrasure east side of the north-east tower, *i.e.*, about 12 inches below high water of spring tides. The partial breach behind the north timber revetment and up to the sand cliff had become filled in a degree with a 'full' of large pebbles collected during the prior two days. The crest of this 'full' was about level with high water of spring tides, and this is the general level of the top of the upper 'full' towards Battery No. 1, so that the shingle mole north of the Castle is now 6 feet to 8 feet lower than in 1856.¹

I have the honour to be, Sir,

Your very obedient Servant,

(Signed) J. B. REDMAN.

5. DOVER EAST-CLIFF SHORE.

H.M. WAR DEPARTMENT AND THE TOWN COUNCIL OF DOVER.

To Lieut.-Colonel Jervois, R.E., Deputy-Inspector of Fortifications.

11 Manchester Buildings, Westminster, S.W., May 7, 1863.

SIR,—In accordance with your instructions of the 14th ultimo, I visited Dover on the 20th, and placed myself in communication with General Stotherd, who lent me a sheet of the Ordnance Survey of the town, with lines showing the degradation produced by the gale of December last upon the East Cliff frontage and the recent ranges of extreme spring tides, as surveyed by his officers, which I have had transferred to the drawing accompanying this report. The General also afforded me every facility in my inquiry, by the production for my inspection of plans and documents at Archcliff Fort, and by his personal explanations of the fullest character. I attended a meeting at noon the same day, summoned by Mr. Knocker, the town clerk, at his offices, consisting of Mr. Worsfold, the Mayor, Captain Noble, Mr. Rees the harbour engineer, and a member of the Town Council, and Mr. Hanvey, the town surveyor. I afterwards inspected the shore accompanied by the last-named gentleman, and again that evening at low water, and also surveyed the condition of the Castle jetty; and the following morning I took the sections (at low water) which accompany this communication, in which I was assisted by Mr. Hanvey and the men at his disposal; from these, and the plan, the general condition of the shore, and the effect of the December gale, will be seen at a glance.

It appeared generally admitted at the above meeting that the Marine Parade and Waterloo Crescent were formerly more exposed than now to the sea from the S.W., the stroke of which has been projected more and more eastward as the Admiralty Pier has been extended seaward, and the East Cliff property has been more exposed of late years from this cause, which has been increased by the recent erection of the harbour jetty, which, by its great height, causes an eddying of the sea eastward, scouring out the shingle forming the natural barrier, and by which the extreme range of the tide at high water, has, from documents placed before me, advanced landward nearly 100 feet from off the centre of Guilford battery to the west side of Arlington House, East Cliff Terrace.

The local 'full' of shingle seen on Section No. 1, and on the plan in front of the esplanade, has gathered there since the gale, said to have travelled from the eastward from the 'full' at the back of the Castle jetty, and of course liable to travel back in an opposite direction.

The harbour stone groyne, or jetty, erected in front of Guilford battery, and now drawing towards completion, takes virtually the position, as respects the harbour frontage, hitherto occupied by the Castle jetty, the same results being traced east of it as to the east of the Castle jetty, as, whatever accumulation of shingle it may tend to promote to the benefit of the harbour frontage west of it, a corresponding sweeping out of the shore may be expected to ensue eastward. This result took place to such an extent during the December gale as to gully out the beach behind

¹ [Mr. Sidney Herbert, then Secretary of War, determined on abandoning the Castle. It was sold, but proved so tough a morsel that it was only lowered down to near ground level. The portion so much written about recently was the mere basement. On the abutment of the drawbridge was the monogram of the great Cecil, Earl of Burleigh.]

the root or commencement of the groyne, which it threatened to isolate, and which has been hastily continued landwards by a temporary stone wall to check this disposition the sea displayed to get behind the groyne, which, from its position and height (9 feet above H. W. springs), causes an increased action of the sea to leeward, and consequent recession of the high-water line to be met by other works of defence eastward.

It will be seen by the plan that it is only the western portion of the East Cliff property that is immediately affected by the recent encroachment of the sea, the triangular 'full' of shingle held in position by the Castle jetty forming a sea barrier to the terrace from Arlington House eastward; should, however, the recession of the shore in front of Guilford battery continue, no steps being taken to arrest the sea, the apex of this triangular accumulation of shingle abutting on Castle jetty will retreat landward and eastward, the inclined line of high water becoming more and more acute, and the frontage defended by the shingle would necessarily become more limited in extent. The stability of this shingle mole depends entirely on the state of repair of the Castle jetty; and when it is considered that the beach is more than 20 feet higher on one side than on the other, it will be seen that it is a vital question in the inquiry.

The small amount of shingle that lies under the lee of Castle jetty to the eastward was during my inspection—

At the high-water 'full' in a line with the East		
Cliff houses, from the platform, of the jetty	12 ft.	below it
In line of garden walls of ditto	20 ft. 6 in.	"
Line of esplanade railing	23 ft.	"
End of doubled part of jetty	18 ft.	"
At next offset in ditto	23 ft.	"
End of main jetty	24 ft.	"
From top of lower jetty or groyne at junction		
with main jetty	18 ft.	"
The crest of the shingle mole on the western		
side being	5 ft.	above ditto
Or a total difference of level of the beach on		
the two sides of the jetty of	29 ft.	

Whatever works of defence may be constructed in front of the War Department frontage to render permanent the sea margin there will have the effect of protecting the property eastward by holding in position the eastern shingle mole; but this ultimately must depend entirely on the Castle jetty for its continued stability; with, however, a natural sea barrier 10 feet above high water, any shore work of defence along the immediate frontage of East Cliff Terrace would be one of supererogation.¹

Having regard to the above, and considering the entire frontage of 1,100 feet between the new harbour groyne and the Castle jetty, it is impossible to disconnect the condition of the Castle jetty from the inquiry, nor would a parallel shore work of defence be applicable to the entire frontage; and having regard to the uncertainty attached to the ultimate enclosure of the bay and the extent to which the Admiralty pier may be projected, and looking to the success of the timber revetment in front of the Ordnance property and the prevailing opinion in favour of such a work, I am disposed to recommend the construction of an oak timber revetment or wharf from the new harbour groyne to Arlington House 600 feet in length, to be carried down to the chalk substratum according to Section No. 1 for the western end of 200 feet, the necessity for which will be apparent when the action of the sea eastward of the Castle jetty is studied; the eastern portion, from its being mainly behind the shingle, may gradually diminish in depth, of which Section No. 2 is an average section.

In connection with the above, a complete doubling of the Castle jetty is necessary on its outer or eastern side, from the first offset or end of the portion formerly doubled at the north end, down to the end of the lofty portion of the jetty, 120 feet in length. The low-water groyne, 165 feet long, requires similar treatment on the east side for its entire length, and on the west side for half its length. In addition to this outer doubling, a large proportion of the wales, braces, and ties require renewal, and the stone hearting to be redispersed where settled or fallen out, and the

¹ [When the works for enclosing Dover Bay are carried out this state of things will cease. They were problematical in 1863.]

planking of the main jetty above, on the western side, requires repairing and heightening, to prevent the shingle passing through the top.

When it is considered that the rateable value of the twenty-eight houses in East Cliff Terrace is, as I was informed, from 3,000*l.* to 4,000*l.* per annum, and its estimated value 60,000*l.*, it will be seen who is interested in the safety of the Castle jetty, which, by an arrangement with H.M. Woods, &c., on the information of the town clerk and harbour engineer, appears to be transferred to the East Cliff proprietors, and the Harbour Board relieved from all responsibility as to its maintenance, its successor, the new stone groyne, being regarded now as the east boundary of the harbour frontage, the one-mile frontage of the harbour trust, hitherto measured from the old pier, called Cheeseman's Head, at the west end, now enclosed by and incorporated with the Admiralty Pier to the Castle jetty, now being defined eastward by the new jetty, and the frontage at that end reduced by 1,100 feet.

I have defined by a line from the shore end of the harbour groyne, and terminating opposite the west side of Arlington House, the line I propose for the revetment.

I estimate the cost of this work at	£4,800
Castle jetty repairs	1,700
	<hr/>
Total	£6,500

As it appears, on the information of the Mayor, that the garden wall of No. 1 East Cliff Terrace was washed down when the sea made certain inroads on this part of the coast about forty years back, the December casualty was not unprecedented.

The maintenance of the Castle jetty is quite as, if not more, important than the construction of the revetment, nor should I recommend any steps being taken with the latter without the works of renewal to the Castle jetty are carried out coincidentally therewith.

Should these works in their entirety, from want of concert between the parties interested, not be carried out, in the event of another gale such as that of December recurring, the result in all probability would be the cutting off the sea road communication, not to say the endangering of the western houses of East Cliff Terrace; the result would also probably recur that the harbour authorities would be compelled again to continue to extend their jetty landward; in effect the foreshore may be expected to retreat and to be lowered to the eastward of the harbour jetty, as may be observed at the Castle jetty, and the longer the construction of the sea-works of defence are postponed, so will the difficulty of maintaining the present sea margin be increased as well as the necessity entailed of continuing such works further eastward.¹

Should the works be postponed for any lengthened period and the shore margin be much abraded and the foreshore lowered, it then may become a question whether the construction of a stone sea wall in continuation of the harbour jetty eastward would not be the best plan to adopt for the western end.²

I have the honour to be, Sir,

Your very obedient Servant,

(Signed) J. B. REDMAN.

War Office, June 3, 1863.

SIR,—With reference to your letter, dated April 2, and the reply thereto of the 14th idem respecting the encroachment of the sea at east cliff, Dover, I am directed

¹ [As the revetment was commenced just four years after, without the author of this report being consulted or knowing aught of its details or execution, it is manifest he is in no way responsible for the subsequent results; nor did he authorise or recommend the mode adopted. Had he been so, the last paragraph of this report shows he might have advised a very different mode of procedure.

He visited Dover in December 1867 for the first time (viz., 4½ years' interval) after making above report, when he found the timber revetment finished. From its great irregularity he doubts if proper land-ties were provided, and now, from the omission of a most important provision—viz., the heavy top paving and other departures from his plan—sufficient reasons appear for its partial failure. Further he has no evidence of the depth of piling or character or mass of concrete backing.]

² [Ultimately done. Since replaced by a stone wall just prior to decease of late town surveyor, Mr. Hanvey.]

by the Secretary of State for War to forward, for the consideration of the Local Board, the report and plan which have been received from Mr. Redman, C.E., and to observe that in the event of Mr. Redman's project meeting the approval of the Town Council, Lord de Grey will be prepared to recommend to the Lords Commissioners of the Treasury that a sum of 1,800*l.*, or about three-elevenths of the whole expense of carrying out that project, shall be paid for from the Army estimates.

The frontage of the whole of the property to be protected is 1,100 feet, that of the War Department being about 300 feet; this proposal will, therefore, be in accordance with the suggestion contained in the letter from this office, dated March 19, 1863.

I am to request the return of the report and plan.

I am, Sir,

Your most obedient Servant,

(Signed) HARTINGTON.

The Town Clerk, Dover.

6. SHEERNESS.

To Lieut.-Colonel Jervois, R.E.

Westminster, S.W., October 31, 1866.

Sir,—In reply to your letter of the 27th instant respecting 'Garrison Point,' I have to report that Colonel Freeth explained to me on the 18th instant, on the spot, the proposal to use the shingle, within certain limits, for filling up the parade of the new fort, and the agent for the contractor for that work attended to point out from whence he proposed to remove shingle.

My attention was directed to the recent accumulation against groynes run out by the contractor and around blocks of stone deposited for the works.

In my report of August 20, 1857, to you on the groynes along the neighbouring shore, I directed attention to the increase of Garrison Point to the westward and that from plans in your possession at Sheerness it appeared that in 1737 the end of the shingle spit was half a mile east of Garrison Point; also that the Point had been resorted to for many years for material for concrete and for roads, &c., for your Department and for the Dockyard.

Taking these facts into consideration, I do not consider that harm would be done by the removal of shingle from the 'fulls' forming the convex horn of the Point, but as the foundations of the fort are only 5 feet below the level of high water of spring tides, it is clear this must be done with great caution. I should recommend that no shingle be removed below the level of high water of neap tides.

It was stated by the contractors' agent that it would not answer their purpose to remove shingle from the eastward of the fort or east of their westernmost groyne on account of transport, so that they would depend entirely on the horn of shingle immediately contiguous to and around the fort.

Within the above limits, viz., from the Gun Wharf to the western groyne and down to the level of high water of neap tides, about 800 yards cube of shingle might be obtained, so that the high-water 'fulls' would have to be renewed six times before the material required would be obtained, as about 5,000 yards are required; but it is fairly argued that the shingle would follow from the eastward as it was removed from the crest, and it is supposed that the requisite material would be thus obtainable in a few months.

The removal should be first from the eastward working westward, so that the travelling shingle would follow on.

The excavation of the shingle should be only in defined and short lengths, say of 20 yards, or about one-fifth of the entire length of the shingle 'horn' on the curve from the Gun Wharf to the west groyne, which is about 110 yards, and the removal of the next length should not be commenced until the sea has begun to repair the breach thus formed with a new 'full'; the wharfing for the support of the contractors' road around the fort forms a protection at its base in the event of the sea passing over the lowered beach at high water of spring tides.

Should the above precautions be taken, I see no objection to the proposition submitted to me.

I am, Sir,

Your obedient Servant,

(Signed) J. B. REDMAN.

7. ISLE OF GRAIN.

To the Secretary of State for War.

Westminster, S.W., February 21, 1867.

SIR,—Acting on instructions from the War Office of August 22 last, accompanied by various plans and sections showing the works in progress at the Isle of Grain and the extent of the encroachment of the sea on the shore, I proceeded to Sheerness on August 27 and made several inspections at low water during the then spring tides. I also again visited the site in October last in reference to borings then in progress, and also again on the completion of the last, to satisfy myself as to the real character of the substratum, respecting which great doubts had been expressed.

In the course of my inquiry I received every assistance from the then commanding R.E. officer at Sheerness, Colonel Freeth, and from the officers at the Isle of Grain fort.

My instructions inform me it is proposed to protect in the most economical manner the foreshore of the property of your Department.

From the plans placed before me and from my inspections I draw the conclusion that the waste of the shore is to a certain extent local, viz., that the material, the London clay and sand and gravel thereon, and the alluvial deposits southwards, are all easily acted on by the sea at high water, and that the material abraded is redistributed upon the foreshore; a comparison of the early plan made for the Board of Ordnance in 1784 with those of the present day shows this, and that the high-water mark is much further inshore and the low-water mark further out. To the north of the fort at the boundary of the property of your Department the sea has gained to the extent of 700 feet and to the eastward of the fort the low-water mark is nearly a corresponding distance further out.

To check this action, I recommend the construction of stone slopes of Kentish rag paving on a bed of concrete, separated into bays by sheet piling, and these again subdivided by lateral piling, as shown on the accompanying drawing.

North and south of the pavement I recommend the construction of two low groynes, as shown at the north end, in a direction N.E. by E. by compass, and that at the south, E.S.E., and two at the north and south ends of the fort frontage, each bearing E.N.E., also opposite the north and south extremities of the battery, that at the north end to bear east by compass, and that at the south to bear E.S.E., viz., six groynes in all.

As regards the frontage of the battery, I do not recommend quite the same treatment as for the rest of the frontage.

For the frontage generally, I consider that the paving should be brought up above high water until it intersects the glacis slopes, and that north and south and between the fort and battery it should be brought up to the level of the adjacent low land or summits of the neighbouring walls, and that the foot or toe of the slopes should be sheet piled, with a deep trench at back for a rough deposit of stone to form an abatement at foot. To the southward this becomes more necessary from the nature of the ground, and the toe will have to be increased in depth more especially corresponding with the frontage of the battery.

Certain borings were taken in 1861, the results of which were placed before me, as also the details of the foundations of the Martello Tower on Grain Spit; from these it was clear that there is following the contour of the hill above a considerable inclination of the London clay to the southward.

Looking to the uncertainty respecting the level of the London clay opposite the battery, I recommended the sinking of two additional boreholes north and south of the battery frontage next the sea, adjacent to and 40 feet west of the two black beacons.

The general result was, at the outer or north beacon for a depth of 35 feet (22 feet below Ordnance datum) nothing but layers of modern alluvion were met with upon a crust of gravel, into which the boring was carried 5 feet, 40 feet in all: this boring was abandoned from the tool's failing. At the inner or south beacon similar material was passed through for 45 feet, when blue clay was reached, and bored into for 7 feet 6 inches, a total depth of 52 feet 6 inches.

From the fact that the pipes were drawn before I had the opportunity of examining the strata in the second or south boring, a third was made at my request 320 feet north of the south beacon and in a line with the other two, which proves that the solid London blue clay is 45 feet from the surface of the ground, or 32 feet from Ordnance datum and 26 feet below low water; from the borings of

1861 the inference might have been drawn that it was at a much greater depth, so that the result of these last borings may be looked on as highly satisfactory, and showing the necessity that existed for their being undertaken.

I estimate the cost for defending the entire frontage with stone slopes, &c., as herein proposed, at 30,000*l.*; to put in extra and deeper work at the foot of the stone slope for 400 yards in length in front of the battery will cost 15,000*l.* in addition, making 45,000*l.* total outlay.

I had (for the battery frontage) considered the mode and probable cost of putting in a retaining wall on piles with sheet piling next the sea down to the blue clay, and also a concrete wall got in by means of caissons of iron down to the clay also; but the great depth of the latter and the large cost induce me to recommend the plan shown upon the accompanying drawing, viz., an increased weight of concrete put in in boxes of sheet piling, the front row driven down to the layer of gravel at the north end and to the surface of the clay at and towards the south end: this will involve sheet piling next the sea 25 feet in length for about one-third the frontage and 36 feet for the rest; the back row may be 10 feet shorter; the areas must be subdivided (in progress) by cross rows of piled planking and the concrete got in through the water after the excavation is dredged out.

I have the honour to be, Sir,

Your obedient Servant,

(Signed) J. B. REDMAN.

G. Copy of Questions.

N.B.—Answers to these questions will in most cases be rendered more precise and valuable by sketches illustrating the points referred to.

1. What part of the English or Welsh Coast do you know well?
2. What is the nature of that coast?
 - a. If cliffy, of what are the cliffs composed?
 - b. What are the heights of the cliff above H.W.M.? Greatest; average; least.
3. What is the direction of the coast-line?
4. What is the prevailing wind?
5. What wind is the most important—
 - a. In raising high waves?
 - b. In piling up shingle?
 - c. In the travelling of shingle?
6. What is the set of the tidal currents?
7. What is the range of tide?
 - (1) Vertical in feet. (2) Width in yards between high and low water.
 - (a) At spring tide; (b) at neap tide.
8. Does the area covered by the tide consist of bare rock, shingle, sand, or mud?
9. If of shingle, state—
 - a. Its mean and greatest breadth.
 - b. Its distribution with respect to tide-mark.
 - c. The direction in which it travels.
 - d. The greatest size of the pebbles.
 - e. Whether the shingle forms one continuous slope, or whether there is a 'spring full' and 'neap full.' If the latter, state their heights above the respective tide-marks.
10. Is the shingle accumulating or diminishing, and at what rate?
11. If diminishing, is this due partly or entirely to artificial abstraction? (See No. 13.)
12. If groynes are employed to arrest the travel of the shingle, state—
 - a. Their direction with respect to the shore-line at that point.
 - b. Their length.
 - c. Their distance apart.
 - d. Their height—
 - (1) When built.
 - (2) To leeward above the shingle.
 - (3) To windward above the shingle.
 - e. The material of which they are built.
 - f. The influence which they exert.
13. If shingle, sand, or rock is being artificially removed, state—
 - a. From what part of the foreshore (with respect to the tidal range) the material is mainly taken.
 - b. For what purpose.
 - c. By whom—Private individuals. Local authorities. Public companies.
 - d. Whether half-tide reefs had, before such removal, acted as natural breakwaters.
14. Is the coast being worn back by the sea? If so, state—
 - a. At what special points or districts.

RATE OF EROSION OF THE SEA-COASTS OF ENGLAND AND WALES. 933

- b. The nature and height of the cliffs at those places.
 - c. At what rate the erosion now takes place.
 - d. What data there may be for determining the rate from early maps or other documents.
 - e. Is such loss confined to areas bare of shingle?
- 15.** Is the bareness of shingle at any of these places due to artificial causes?
- a. By abstraction of shingle.
 - b. By the erection of groynes, and the arresting of shingle elsewhere.
- 16.** Apart from the increase of land by increase of shingle, is any land being gained from the sea? If so, state—
- a. From what cause, as embanking salt-marsh or tidal foreshore.
 - b. The area so regained, and from what date.
- 17.** Are there 'dunes' of blown sand in your district? If so, state—
- a. The name by which they are locally known.
 - b. Their mean and greatest height.
 - c. Their relation to river mouths and to areas of shingle.
 - d. If they are now increasing.
 - e. If they blow over the land; or are prevented from so doing by 'bent grass' or other vegetation, or by water channels.
- 18.** Mention any reports, papers, maps, or newspaper articles that have appeared upon this question bearing upon your district (copies will be thankfully received by the Secretaries).
- 19.** Remarks bearing on the subject that may not seem covered by the foregoing questions.

- Annual winding clock, an, with torsion pendulum, by W. H. Douglas, 823.
- Antarctic regions, third report of the Committee for drawing attention to the desirability of further research in the, 316.
- Anthropological Section, Address by Lieut.-Gen. Pitt-Rivers to the, 825.
- Anthropometric laboratory at Manchester, observations made in the, by G. W. Bloxam and Dr. J. G. Garson, 854.
- Antilles, the nucleal ranges of the, archæan characters of the rocks of, by Dr. P. Frazer, 654.
- Archæan characters of the rocks of the nucleal ranges of the Antilles, by Dr. P. Frazer, 654.
- Archæan time, a review of the alleged evidence of life on the earth in, by Rev. A. Irving, 679.
- Armstrong (Prof. H. E.) on the present methods of teaching chemistry, 73; on isomeric naphthalene derivatives, 96; on the teaching of science in elementary schools, 164; on electrolysis in its physical and chemical bearings, 339; note on Dr. Arrhenius's reply to his criticisms regarding the dissociation theory of electrolysis, 355.
- Armstrong's, Prof., criticisms regarding the dissociation theory of electrolysis, reply to, by S. Arrhenius, 352; note thereon, by Prof. H. E. Armstrong, 355.
- Arrhenius (S.), reply to Prof. Armstrong's criticisms regarding the dissociation theory of electrolysis, 352; note thereon by Prof. H. E. Armstrong, 355.
- Asia, Western, the early races of, by Major C. R. Conder, 855.
- Asia Minor, discoveries in, by J. T. Bent, 856.
- Associative economics applied to colonisation, by W. L. Rees, 762.
- *Assurance, old age, and sickness, for the mercantile and professional classes, by F. Norfolk, 780.
- *Atlas Mountains, notes from the, by J. Thomson, 745.
- Atomic weight of oxygen, Dr. A. Scott on the, 631.
- *Atomic weights, the logarithmic law of, Dr. G. J. Stoney on the proof of, 562.
- *—, the logarithmic law and its connection with the, by Dr. G. J. Stoney, 630.
- Australian message-sticks and messengers, by A. W. Howitt, 842.
- Automatic fire-damp detector, J. W. Swan on an, 817.
- Ayrton (Prof.) on standards for use in electrical measurements, 55.
- *— and Profs. Sir W. Thomson and Perry, electrometric determination of 'v,' 616.
- Azorean archipelago, the recent volcanic structure of the, O. H. Howarth on, 671.
- Babbage (the late Charles, F.R.S.), on the mechanical arrangements of the analytical engine of, by Maj.-Gen. H. P. Babbage, 616.
- Bahamas, the flora of the, report on, 361.
- Baker (J. G.) on the flora of the Bahamas, 361.
- Bale (F.), recovery of the ammonia and chlorine in the ammonia-soda process, 638.
- Balfour (Prof. B.) on the steps taken for establishing a botanical station at Peradeniya, Ceylon, 421.
- Ball (J.) on our present knowledge of the flora of China, 420.
- Ball (Sir R. S.) on the desirability of introducing a uniform nomenclature for the fundamental units of mechanics, 27.
- Ball (Prof. V.) on the provincial museums of the United Kingdom, 124.
- Banking statistics, by W. Botly, 760.
- Barber (C. A.) on the development of the bulb in *Laminaria bulbosa*, 710; on *Pachytheca*, a silurian alga of doubtful affinities, 711.
- Baron (Rev. R.) on the flora of Madagascar, 724.
- Barrington (R. M.) on the migration of birds, 146.
- Barron (Dr. G. B.), the constitutional characteristics of those who dwell in large towns, as relating to degeneracy of race, 836.
- Barry (J. W.), the Barry docks, 795.
- Barry docks, the, by J. W. Barry, 795.
- Bassani (Prof. F.), notes of some researches on the fossil fishes of Chiavòn, Vicentino (stratum of Sotzka, lower miocene), 675.

- Bassett (A. B.), waves in a viscous liquid, 563.
- *Bath, the vital and commercial statistics of, by F. Norfolk, 780.
- Bath oolite, the extension of the, under London, as shown by a deep boring at Streatham, W. Whitaker on, 656.
- Bauefman (H.) on the volcanic phenomena of Vesuvius and its neighbourhood, 320.
- Baynes (R. E.) on the desirability of introducing a uniform nomenclature for the fundamental units of mechanics, 27.
- Beaumont (W. W.), the efficiency of steam at high pressures and the Carnot theorem, 820.
- *Bechuanaland and the Land of Ophir, by Rev. J. Mackenzie, 745.
- Becker (Miss L.) on the teaching of science in elementary schools, 164.
- *Beddard (F. E.), contributions to the anatomy of the Tubificidæ, 723.
- Beddoe (Dr. J.) on the effects of different occupations and employments on the physical development of the human body, 100; the physique of the Swiss as influenced by race and by media, 837; on human bones discovered by Gen. Pitt-Rivers at Woodcuts, Rotherley, &c., 839.
- Beds exposed in the Southampton new dock excavation, by T. W. Shore, 672.
- Bedson (Prof. P. P.) on photographing hydrogen and chlorine bulbs by aid of the flash of light which caused their explosion, 633.
- *Bees and wasps, solitary, the instincts of, Sir J. Lubbock on, 706.
- Bell (A.) on the 'manure' gravels of Wexford, 133.
- Bell (Prof. F. J.) on the echinodermata of the Sea of Bengal, 718.
- Ben Nevis, meteorological observations on, report of the Committee for co-operating with the Scottish Meteorological Society in making, 49.
- Bent (J. T.) on the prehistoric race in the Greek islands, 99; sun-myths in modern Hellas, 850; discoveries in Asia Minor, 856.
- *Benzene, the constitution of, Van't Hoff's hypothesis and, J. E. Marsh on, 631.
- Beryl, the temperature at which it is decolorised, J. Joly on, 684.
- Bidwell (S.) on electrolysis in its physical and chemical bearings, 339.
- Bile, the rate of secretion and constitution of the, the effect of various substances upon, by Dr. W. J. Collins, 728.
- Biological Section, Address by W. T. Thiselton-Dyer to the, 686.
- Blackburn (Miss H.), Irishwomen's industries, 772.
- Blake (Prof. J. F.) on the microscopic structure of the older rocks of Anglesey, 367.
- Blaps mortisaga* (Coleoptera), the odorous apparatus of the, by Prof. G. Gibson, 727.
- Bloxam (G. W.) on the prehistoric race in the Greek islands, 99; on the effects of different occupations and employments on the physical development of the human body, 100; on the North-western tribes of the dominion of Canada, 233.
- and Dr. J. G. Garson, observations made in the anthropometric laboratory at Manchester, 854.
- **Blumenbachia Hieronymi*, Urban, the contrivances for the seed protection and distribution in, W. Gardiner on, 716.
- Boats, &c., the disengaging of, E. J. Hill on, 807.
- *Bolland (Col. J. H.), photographic and photozincographic processes employed in the Ordnance Survey, 746.
- Bonghi (Signor), l'organisation et la statistique de l'enseignement technique secondaire en Italie, 774.
- Bonney (Prof. T. G.) on the erratic blocks of England, Wales, and Ireland, 101; on the microscopic structure of the older rocks of Anglesey, 367; on a boulder of granitoid gneiss or gneissoid granite in the Halifax hard-bed coal, 661.
- Botly (W.), agricultural, commercial, industrial, and banking statistics 760.
- Bott (Dr. W.), the determination of vapour-densities at high temperatures and under reduced pressure, 632.
- and J. B. Miller, further researches on the pyrocresols, 642.
- Bottomley (J. T.) on standards for use in electrical measurements, 55; on electrolysis in its physical and chemical bearings, 339.
- *Boulder-clay, a high level, in the Midlands, by Dr. H. W. Crosskey, 656.
- Bourne (S.) on the teaching of science in elementary schools, 164; on the best method of ascertaining and measuring variations in the value of the monetary standard, 181; on the statistical data available for determining the amount of the precious metals in use as money, &c., 219; index-numbers as illustrating the progressive exports of British produce and manufactures, 536.
- Bovey (Prof. H. T.) on promoting tidal observations in Canada, 27.

- Bower (Prof.) on the steps taken for establishing a botanical station at Peradeniya, Ceylon, 421; *on the morphology of the pitcher of *nepenthes*, 702.
- Boynton (T.) on an ancient sea-beach near Bridlington Quay, 328.
- Boys (C. V.) on the work of the Differential Gravity Meter Committee, 72.
- Brain (F.), electricity as applied to mining, 815.
- Bramwell (Lord), Address to the Section of Economic Science and Statistics by, 749.
- Bramwell (Sir F. J.) on the advisability and possibility of establishing in other parts of the country observations upon the prevalence of earth tremors similar to those now being made in Durham, 522.
- Bridge design, mechanical pathology considered in its relation to, by G. H. Thomson, 793.
- Bristol coal-field, the northern section of the, by H. Cossham, 659.
- British Association and other standard coils, on the permanence of the original standards of resistance of the, by R. T. Glazebrook and T. C. Fitzpatrick, 56.
- British mineral and thermal waters, a list of works referring to, by W. H. Dalton, 859.
- Brontops robustus*, restoration of, from the miocene of America, by Prof. O. C. Marsh, 706.
- Brown (Prof. Crum) on meteorological observations on Ben Nevis, 49; on electrolysis in its physical and chemical bearings, 339.
- Brown (J.) on electrolysis in its physical and chemical bearings, 339; on figures produced by electric action on photographic dry plates, 565.
- Brown (S.) on locusts in Cyprus, 716.
- Buchan (Dr. A.) on meteorological observations on Ben Nevis, 49; on the marine biological station at Granton, 319; on arranging an investigation of the seasonal variations of temperature in lakes, rivers, and estuaries, 326.
- Buchanan (J. Y.) on arranging an investigation of the seasonal variations of temperature in lakes, rivers, and estuaries, 326.
- Buckland (Miss A. W.), necklaces in relation to prehistoric commerce, 849; the monument known as 'King Orry's Grave' compared with tumuli in Gloucestershire, 854.
- Bucklandium diluvii*, König, a siluroid fish from the London clay of Sheppey, A. S. Woodward on, 679.
- Bund (J. W. W.), the Severn watershed, 799.
- Burning by lightning of a magnet on a generating dynamo, Dr. A. Traill on the, 615.
- C.G.S. units of measurement, W. H. Preece on the, 616.
- Callaway (Dr. C.), further notes on the origin of the crystalline schists of Malvern and Anglesey, 653; sketch of the geology of the crystalline axis of the Malvern Hills, 654.
- *Cameroons, the, by H. H. Johnston, 745.
- Canada, tidal observations in, fourth report of the Committee for promoting, 27.
- Canal lift, an improved, S. Lloyd on, 797.
- Canary islands, the ancient inhabitants of the, by J. H. Stone, 851.
- Caoutchouc and other colloids, the molecular weight of, Dr. J. H. Gladstone and W. Hibbert on, 640.
- *Cape Guardafui, sea temperatures in the neighbourhood of, by Lieut.-Gen. Strachey, 738.
- Carbonic acid in the atmosphere, the relation of the percentage of, to the life and growth of plants, Rev. A. Irving on, 661.
- Carboniferous rocks, the lower, of Gloucestershire, E. Wethered on, 657.
- Carnot theorem, the, and the efficiency of steam at high pressures, by W. W. Beaumont, 820.
- Carpenter (W. L.) on the desirability of introducing a uniform nomenclature for the fundamental units of mechanics, 27; on the best means of comparing and reducing magnetic observations, 28; comparison of Gassner's dry cells with Leclanché's, 566.
- and Prof. Balfour Stewart, results of a comparison between the wind values and declination disturbances at the Kew Observatory, 28.
- Carpmael (C.) on promoting tidal observations in Canada, 27; on the best means of comparing and reducing magnetic observations, 28.
- Carruthers (W.) on the flora of the Bahamas, 361; on our present knowledge of the flora of China, 420; on the steps taken for establishing a botanical station at Peradeniya, Ceylon, 421; on the present state of our knowledge of the zoology and botany of the West India islands, and on the steps taken to investigate ascertained deficiencies in the fauna and flora, 437.
- Cash (W.) on the flora of the carboniferous rocks of Lancashire and West Yorkshire, 150; on an ancient sea-beach near Bridlington Quay, 328.

- Catenaries, orbits, and curved rays, Prof. J. D. Everett on the relations between, 581.
- *Cats with an extra number of toes, heredity in, by E. B. Poulton, 707.
- Celtic earthworks in Hampshire, in reference to the density of the Celtic population, by T. W. Shore, 852.
- Centres of finite twist and stretch, Prof. R. W. Genese on, 579.
- Cephalopods and gasteropods, some Devonian, Rev. G. F. Whidborne on, 680.
- Chadwick (E.), the Malthusian theory, 777; amendments founded on experiences submitted for the Local Government Bill, 779.
- *Chemical problems presented by living bodies, discussion on the, 631.
- Chemical Section, Address by Prof. W. A. Tilden to the, 620.
- Chemistry, the present methods of teaching, report on, 73.
- Chemistry as a school subject, by Rev. A. Irving, 634.
- Cherriman (Prof. J. B.) on promoting tidal observations in Canada, 27.
- Chest-types, notes on, by Dr. G. W. Hambleton, 849.
- China, the flora of, report on our present knowledge of, 420.
- *Chindwin river, Upper Burmah, explorations on the, in 1886-87, by Col. Woodthorpe, 741.
- Choptank river, Maryland, U.S.A., notes on the shell-mounds and ossuaries of the, by Chev. R. E. Reynolds, 845.
- Christie (W. H. M.) on the best means of comparing and reducing magnetic observations, 28.
- Christmas Island, the natural history of, J. J. Lister on, 708.
- Chrystal (Prof. G.) on the best means of comparing and reducing magnetic observations, 28; on standards for use in electrical measurements, 55; on the work of the Differential Gravity Meter Committee, 72; on the marine biological station at Granton, 319; on arranging an investigation of the seasonal variations of temperature in lakes, rivers, and estuaries, 326.
- Cider, Somersetshire, by J. Higgins, 759.
- Clarke (Maj.-Gen. Sir A.), on the erosion of the sea-coasts of England and Wales, 898.
- Clarke (W. E.) on the migration of birds, 146.
- Clausius (Prof.), the authorship of electrolytic theory, 346.
- Clayden (A. W.), perspective maps and common maps, 740.
- Claypole (Prof. E. W.) on some recent investigations into the condition of the interior of the earth, 669.
- Cleghorn (Dr.) on the researches on food-fishes at the St. Andrews marine laboratory, 141.
- Cleland (Prof.) on the researches on food-fishes at the St. Andrews marine laboratory, 141.
- Click mill, the old Orkney, by Prof. A. Jamieson, 807.
- Clock, an annual winding, with torsion pendulum, by W. H. Douglas, 823.
- *Closed-chain formulæ, J. E. Marsh on, 631.
- Clyde sea area, the salinity of the, by Dr. H. R. Mill, 738.
- Coal and iron industries, the effect of mining royalties on, by Prof. W. R. Sorley, 755.
- Codrington (Rev. R. H.), social regulations in Melanesia, 843.
- Collins (Dr. W. J.), the effect of various substances upon the rate of secretion and constitution of the bile, 728.
- Colour-blindness, Dr. K. Grossmann on, 838.
- Combustion in explosions, the incompleteness of, by Prof. H. B. Dixon and H. W. Smith, 632.
- Commercial statistics, by W. Botly, 760.
- *Competition, the tendency of, to result in monopoly, by Prof. Foxwell, 762.
- *Concave gratings, recent progress in the use of, for spectrum analysis, by Prof. H. A. Rowland, 566.
- Conder (Major C. R.), remarks on Mr. Tomkins's paper on the geography of the region from the Nile to the Euphrates as known to the ancient Egyptians, 743; on the early races of Western Asia, 855.
- Conduction of alloys and solid sulphides, Dr. J. H. Gladstone and W. Hibbert on the, 347.
- Conservation of heat in volcanic chimneys, Dr. H. J. Johnston-Lavis on the, 666.
- Constitutional characteristics, the, of those who dwell in large towns, as relating to degeneracy of race, by Dr. G. B. Barron, 836.
- Continental shelf, sea temperatures of the, by Dr. H. R. Mill, 739.
- Contortions of strata, a probable cause of, Dr. C. Ricketts on, 684.
- Contractile vacuole in plants and animals, preliminary note on the functions and homologies of the, by Prof. M. M. Hartog, 714.
- Copper, the rate of solution of, in acids, V. H. Veley on, 638.
- Copper-tin alloys, the composition of, by A. P. Laurie, 637.

- Coral fungia, some points in the natural history of the, W. E. Hoyle on, 717.
- Coral reefs, discussion on, 718.
- Cordeaux (J.) on the migration of birds, 146.
- Corporal penance, the survival of, by O. H. Howarth, 849.
- Corresponding Societies Committee, report of the, 255.
- *Cosmogony, on theories of, and on the mechanical conditions of a swarm of meteorites, by Prof. G. H. Darwin, 590.
- Cossham (H.), the northern section of the Bristol coal-field, 659.
- Cowles aluminium process, recent developments of the, by W. Anderson, 809.
- Cowper (E. A.) on the advisability and possibility of establishing in other parts of the country observations upon the prevalence of earth tremors similar to those now being made in Durham, 522; an improved seismograph, 818.
- Creak (Capt.) on the best means of comparing and reducing magnetic observations, 28.
- Cretaceous fish-fauna of Mount Lebanon, a comparison of the, with that of the English chalk, by A. S. Woodward, 678.
- Crompton (R. E.) on recent developments of the Cowles aluminium process, 809.
- Crookes (Mr.) on electrolysis in its physical and chemical bearings, 339.
- Crosskey (Dr. H. W.) on the erratic blocks of England, Wales, and Ireland, 101; on the circulation of underground waters, 145; on the teaching of science in elementary schools, 164; *on a high level boulder-clay in the Midlands, 656.
- Crustaceans, some Devonian, Rev. G. F. Whidborne on, 681.
- Crystalline axis of the Malvern Hills, Dr. C. Callaway on the geology of the, 654.
- Crystalline schists of Malvern and Anglesey, further notes on the origin of the, by Dr. C. Callaway, 653.
- Crystals of calcium oxide and magnesium oxide, the formation of, in the oxy-hydrogen flame, J. Joly on, 634.
- Culverwell (E. P.) on the desirability of introducing a uniform nomenclature for the fundamental units of mechanics, 27.
- Cunningham (D.) on arranging an investigation of the seasonal variations of temperature in lakes, rivers, and estuaries, 326.
- Cunningham (J. T.) on some teleostean ova, and their development, 703.
- Curved rays, orbits, and catenaries, Prof. J. D. Everett on the relations between, 581.
- Cyprus, locusts in, S. Brown on, 716.
- *Dairy industry, by G. Gibbons, 778.
- *D'Almeida (W. B.) on Pahang, an independent state in the Malayan peninsula, 747.
- Dalton (W. H.), a list of works referring to British mineral and thermal waters, 859.
- Danks (Rev. B.), marriage customs of the New Britain group, 847.
- Darwin (Prof. G. H.) on the best means of comparing and reducing magnetic observations, 28; on the advisability and possibility of establishing in other parts of the country observations upon the prevalence of earth tremors similar to those now being made in Durham, 522; *on the mechanical conditions of a swarm of meteorites, and on theories of cosmogony, 590.
- *Darwin (H.) on the effects of different occupations and employments on the physical development of the human body, 100.
- Davey (H.), a new form of air-compressor for variable pressures, 824.
- Davis (J. W.) on the prehistoric inhabitants of the British islands, 289; on an ancient sea-beach near Bridlington Quay, 328.
- Dawkins (Prof. W. Boyd) on the erratic blocks of England, Wales, and Ireland, 101; on the work of the Corresponding Societies Committee, 255; on the prehistoric inhabitants of the British islands, 289; Address to the Geological Section by, 644.
- Dawson (Dr. G. M.) on the North-western tribes of the dominion of Canada, 233.
- Dawson (Major H. P.), magnetic disturbances at Fort Rae in 1882-83, 31.
- De Rance (C. E.) on the erratic blocks of England, Wales, and Ireland, 101; on the circulation of underground waters, 145; on the erosion of the sea-coasts of England and Wales, 898.
- Declination disturbances, wind values and, at the Kew Observatory, results of a comparison between the, by Prof. Balfour Stewart and W. L. Carpenter, 28.
- *Deep-sea tow net, W. E. Hoyle on a, 717.
- De la Rive (L.) on composition of sensation and notion of space, 585.
- *Dennett (Q. E.), through Kakongo, 745.
- Denton (J. B.) on the replenishment of the underground waters of the permeable formations of England, 797.
- Development of institutions, on a method of investigating the; applied to laws of marriage and descent, by Dr. E. B. Tylor, 840.
- Dewar (Prof.) on standards of light, 39.

- Dewar (Prof.) and Prof. Liveing on the absorption spectrum of oxygen, 576.
- Dibdin (Mr.) on standards of light, 39.
- Differential gravity meter, a good, third report of the Committee for inviting designs for, in supersession of the pendulum, 72.
- Diffusion photometer, J. Joly on a, 578.
- **Dinosauria* of Europe and America, comparison of the principal forms of, by Prof. O. C. Marsh, 660.
- Discoveries in Asia Minor, by J. T. Bent, 856.
- Disengaging of boats, &c., E. J. Hill on the, 807.
- Dissociation, Rev. A. Irving on, 630.
- Dissociation theory of electrolysis, reply to Prof. Armstrong's criticisms regarding the, by S. Arrhenius, 352; note thereon, by Prof. H. E. Armstrong, 355.
- Dixon (E. T.) on geometry of four dimensions, 618.
- Dixon (Prof. H. B.) on standards of light, 39; on electrolysis in its physical and chemical bearings, 339.
- and H. W. Smith, the incompleteness of combustion in explosions, 632.
- Douglas (W. H.), an annual winding clock, with torsion pendulum, 823.
- Douglass (Sir J.) on standards of light, 39; on the erosion of the sea-coasts of England and Wales, 898.
- Dowson (J. E.), gaseous fuel, 805.
- Dunn (J. T.) on the present methods of teaching chemistry, 73.
- Dunn (T. W.), education: a chapter of economics, 773.
- Dunstan (Prof. W. R.) on the present methods of teaching chemistry, 73.
- *Dynamo, a, on controlling the direction of rotation of, by A. Winter, 824.
- Early races of Western Asia, Major C. R. Conder on the, 855.
- Earth, the interior of the, some recent investigations into the condition of, Prof. E. W. Claypole on, 669.
- Earth tremors, report on the advisability and possibility of establishing in other parts of the country observations upon the prevalence of, similar to those now being made in Durham, 522.
- Earthquake and volcanic phenomena of Japan, eighth report on the, 422.
- Easton (E.), on the erosion of the sea-coasts of England and Wales, 898.
- Echinodermata of the Sea of Bengal, Prof. F. J. Bell on the, 718.
- Eclipse of the moon, some photographs of an, F. Greene on, 617.
- Economic Science and Statistics, Address by Lord Bramwell to the Section of, 749.
- Economic theory, the relations between sliding scales and, by L. L. Price, 523.
- Economy in education and in writing, by E. Pitman, 776.
- Edgeworth (Prof. F. Y.) on the best method of ascertaining and measuring variations in the value of the monetary standard, 181; memorandum on the proposed calculation of index-numbers, 188; on the statistical data available for determining the amount of the precious metals in use as money, &c., 219; on Jevons' method of ascertaining the number of coins in circulation, 224; on the statistics of examination, 763.
- Edmunds (H.), the graphophone, 792; on a system of electrical distribution, 813.
- Education: a chapter of economics, by T. W. Dunn, 773.
- , agricultural, by Prof. J. Long, 776.
- Education and writing, economy in, by E. Pitman, 776.
- Electric action, figures produced by, on photographic dry plates, J. Brown on, 565.
- Electric light applied to night navigation upon the Suez Canal, by R. P. Sellon, 814.
- Electric lighting in America, by Prof. G. Forbes, 813.
- Electric safety lamps for miners, by N. Watts, 816.
- Electrical distribution, a system of, H. Edmunds on, 813.
- Electrical measurements, report of the Committee for constructing and issuing practical standards for use in, 55; on the permanence of the original standards of resistance of the British Association and of other standard coils, 56.
- *Electrical resistance, standards of, R. T. Glazebrook on, 616.
- Electricity, the application of, to the working of a 20-ton travelling crane, by W. Anderson, 808.
- *—, the measurement of, in a house to house supply, by W. Lowrie, 814.
- , the transference of, within a homogeneous solid conductor, Prof. Sir W. Thomson on, 570.
- , static, a vortex analogue of, by Prof. W. M. Hicks, 577.
- Electricity as applied to mining, by F. Brain, 815.
- Electro-calorimetry, by Prof. W. Stroud and W. W. H. Gee, 565.
- Electro-chemical thermo-dynamics, by Prof. Willard Gibbs, 343.
- Electrodes, small, the polarisation of, in dilute sulphuric acid, Dr. F. Richarz on, 350.

- Electrolysis, the dissociation theory of, reply to Prof. Armstrong's criticisms regarding, by S. Arrhenius, 352; note thereon by Prof. H. E. Armstrong, 355.
- Electrolysis in its physical and chemical bearings, third report on, 339.
- Electrolysis of thallium trisulphide, Dr. J. H. Gladstone and W. Hibbert on the, 349.
- Electrolytes, the accuracy of Ohm's law in, Prof. Fitzgerald and F. Trouton on, 341.
- Electrolytic theory, the authorship of, by Prof. Clausius, 346.
- Electro-magnetic induction of incomplete circuits, a simple hypothesis for, with consequent equations of electric motion in fixed homogeneous or heterogeneous solid matter, by Prof. Sir W. Thomson, 567.
- *Electro-magnetic waves, on a modification of Maxwell's equations of, by Prof. H. A. Rowland, 617.
- , on the measurement of the length of, by Prof. O. J. Lodge, 567.
- *Electrometric determination of 'v,' by Profs. Sir W. Thomson, Ayrton, and Perry, 616.
- Ellis (W.) on the best means of comparing and reducing magnetic observations, 28.
- El-Wedj, mission to, by Capt. C. Surtees, 747.
- *Elwes (Capt. W. J.), a new route from India to Tibet, 741.
- *Embryos, certain adaptations for the nutrition of, F. W. Oliver on, 710.
- Enseignement technique secondaire en Italie, l'organisation et la statistique de l', by Signor Bonghi, 774.
- Erosion of the sea-coasts of England and Wales, the rate of, and the influence of the artificial abstraction of shingle or other material in that action, report on, 898.
- Erratic blocks of England, Wales, and Ireland, sixteenth report on the, 101.
- Errors of the argument of statistical tables, J. Kleiber on the, 618.
- Eruption, the late, in the island of Vulcano, Drs. T. Anderson and H. J. Johnston-Lavis on, 664.
- Etheridge (R.) on the 'manure' gravels of Wexford, 133; on the fossil phyllopoda of the palæozoic rocks, 173; on the earthquake and volcanic phenomena of Japan, 422.
- Etna, the occurrence of leucite at, Dr. H. J. Johnston-Lavis on, 669.
- Etruscans, Pelasgians, and Iberians: their relations to the founders of the Chaldean and Egyptian civilisations, by J. S. S. Glennie, 857.
- Evans (Dr. J.) on the work of the Corresponding Societies Committee, 255; on the prehistoric inhabitants of the British islands, 289; on the advisability and possibility of establishing in other parts of the country observations upon the prevalence of earth tremors similar to those now being made in Durham, 522.
- Everett (Prof. J. D.) on the desirability of introducing a uniform nomenclature for the fundamental units of mechanics, 27; on standards for use in electrical measurements, 55; on the relations between orbits, catenaries, and curved rays, 581.
- Ewart (Prof.) on the researches on food-fishes at the St. Andrews marine laboratory, 141.
- Ewing (Prof.) on the advisability and possibility of establishing in other parts of the country observations upon the prevalence of earth tremors similar to those now being made in Durham, 522.
- Examination, the statistics of, Prof. F. Y. Edgeworth on, 763.
- Explosions, the incompleteness of combustion in, by Prof. H. B. Dixon and H. W. Smith, 632.
- Factory industries, the suitability of small towns for, by R. R. Tanner, 767.
- *Fauna of the Firth of Clyde, W. E. Hoyle on the, 717.
- Fayum and Raian basins, the, by Cope Whitehouse, 746.
- Fermat's theorem, recurring decimals and, Prof. R. W. Genese on, 580.
- Ferns, abnormal, hybrids, and their parents, by E. J. Lowe and Col. Jones, 713.
- Figures produced by electric action on photographic dry plates, J. Brown on, 565.
- Fire-damp detector, an automatic, J. W. Swan on, 817.
- *Firth of Clyde, the fauna of the, W. E. Hoyle on, 717.
- Fitzgerald (Prof. G. F.) on the desirability of introducing a uniform nomenclature for the fundamental units of mechanics, 27; on standards for use in electrical measurements, 55; on arranging an investigation of the seasonable variations of temperature in lakes, rivers, and estuaries, 326; on electrolysis in its physical and chemical bearings, 339; Address to the Mathematical and Physical Section by, 557.
- and F. Trouton on the accuracy of Ohm's law in electrolytes, 341.

- Fitzgerald (M. F.), steam engine diagrams, 819.
- Fitzpatrick (C. T.) and R. T. Glazebrook on the permanence of the original standards of resistance of the British Association and of other standard coils, 56.
- Fleming (Dr. J. A.) on the desirability of introducing a uniform nomenclature for the fundamental units of mechanics, 27; on standards for use in electrical measurements, 55; on electrolysis in its physical and chemical bearings, 339.
- Flora of China, report on our present knowledge of the, 420.
- Flora of Madagascar, Rev. R. Baron on the, 724.
- Flora of the Bahamas, report on the, 361.
- Flora of the carboniferous rocks of Lancashire and West Yorkshire, report on the, 150.
- Flower (Prof.) on the desirability of further research in the Antarctic regions, 316; on the present state of our knowledge of the zoology and botany of the West India islands, and on the steps taken to investigate ascertained deficiencies in the fauna and flora, 437.
- Flux and reflux of water in open channels or in pipes or other ducts, Prof. J. Thomson on, 574.
- Food-fishes, report of the Committee for continuing the researches on, at the St. Andrews marine laboratory, 141.
- Forbes (Prof. G.) on standards of light, 39; electric lighting in America, 813.
- Forbes (Mr.) on our present knowledge of the flora of China, 420.
- *Ford (P. H.), the Transvaal, or South African Republic, 745.
- Fordham (H. G.) on the erratic blocks of England, Wales, and Ireland, 101; on the provincial museums of the United Kingdom, 124; on the work of the Corresponding Societies Committee, 255.
- *Formosa: characteristic traits of the islands and its aboriginal inhabitants, by G. Taylor, 747.
- Fossil arctic plants from the lacustrine deposit at Hoxne, in Suffolk, by C. Reid and H. N. Ridley, 674.
- Fossil fishes of Chiavon, Vicentino (stratum of Sotzka, lower miocene), notes of some researches on the, by Prof. F. Bassani, 675.
- Fossil phyllopoda of the palæozoic rocks, sixth report on the, 173.
- Fossils of the limestones of South Devon, Rev. G. F. Whidborne on some, 681.
- Foster (Prof. G. C.) on the desirability of introducing a uniform nomenclature for the fundamental units of mechanics, 27; on standards of light, 39; on standards for use in electrical measurements, 55; on electrolysis in its physical and chemical bearings, 339.
- Foster (Prof. M.) on arrangements for assisting the Marine Biological Association laboratory at Plymouth, 94; on the occupation of a table at the zoological station at Naples, 150; on the physiology of the lymphatic system, 363; on the steps taken for establishing a botanical station at Peradeniya, Ceylon, 421.
- Fourier's law of diffusion, five applications of, illustrated by a diagram of curves with absolute numerical values, by Prof. Sir W. Thomson, 571.
- Fowler (G. H.) on the development of the oviduct and connected structures in certain fresh-water teleostei, 338.
- Foxwell (Prof. H. S.) on the best method of ascertaining and measuring variations in the value of the monetary standard, 181; on the statistical data available for determining the amount of the precious metals in use as money, &c., 219; *the tendency of competition to result in monopoly, 762.
- Frankland (Prof.) on electrolysis in its physical and chemical bearings, 339.
- Frazer (Dr. P.), archæan characters of the rocks of the nucleal ranges of the Antilles, 654; on a specimen of quartz from Australia and three specimens of oligoclase from North Carolina exhibiting curious optical properties, 655.
- Friction of metal coils, the, by Prof. H. Shaw and E. Shaw, 540.
- Fundamental units of mechanics, report of the Committee for considering the desirability of introducing a uniform nomenclature for the, and for co-operating with other bodies engaged in similar work, 27.
- Funeral rites and ceremonies of the Nicobar islanders, by E. H. Man, 844.
- Gadow (Dr. H.) on the nature of the geological terrain as an important factor in the geographical distribution of animals, 707.
- Galton (Sir D.) on the circulation of underground waters, 145; on the work of the Corresponding Societies Committee, 255.
- Galton (F.) on the work of the Corresponding Societies Committee, 255.
- Gardiner (J.) on the occupation of the table at the zoological station at Naples, 152.
- *Gardiner (W.) on the contrivances for the seed protection and distribution in *Blumenbachia Hieronymi*, Urban, 716.

- Garnett (Prof. W.) on standards for use in electrical measurements, 55.
- Garson (Dr. J. G.) on the prehistoric race in the Greek islands, 99; on the effects of different occupations and employments on the physical development of the human body, 100; on the work of the Corresponding Societies Committee, 255; human remains from Wiltshire, 839.
- and G. W. Bloxam, observations made in the Anthropometric laboratory at Manchester, 854.
- Gas analysis apparatus, a new, by Dr. W. W. J. Nicol, 632.
- Gaseous fuel, by J. E. Dowson, 805.
- Gassner's dry cells, comparison of, with Leclanché's, by W. L. Carpenter, 566.
- Gasteropods and cephalopods, some Devonian, Rev. G. F. Whidborne on, 680.
- Gaudry (Prof. A.) on the gigantic size of some extinct tertiary mammalia, 660.
- Gee (W. W. H.) and Prof. W. Stroud, electro-calorimetry, 565.
- Genese (Prof. R. W.) on the desirability of introducing a uniform nomenclature for the fundamental units of mechanics, 27; on centres of finite twist and stretch, 579; on recurring decimals and Fermat's theorem, 580.
- Geographical distribution of animals, the nature of the geological terrain as an important factor in the, Dr. H. Gadow on, 707.
- Geographical Section, Address by Col. Sir C. W. Wilson to the, 729.
- *Geographical terminology, note on, by H. J. Mackinder, 746.
- Geography, the, of the region from the Nile to the Euphrates as known to the ancient Egyptians, notes on, by Rev. H. G. Tomkins, 741.
- Geological photography, local, O. W. Jeffs on, 653.
- Geological Section, Address by Prof. W. Boyd Dawkins to the, 644.
- Geological terrain, the nature of the, as an important factor in the geographical distribution of animals, Dr. H. Gadow on, 707.
- Geology of Somerset, some points of interest in the, by W. A. E. Ussher, 659.
- Geometry of four dimensions, E. T. Dixon on, 618.
- *Gibbons (G.), dairy industry, 778.
- Gibbs (Prof. Willard), electro-chemical thermo-dynamics, 343.
- Giffen (R.) on the best method of ascertaining and measuring variations in the value of the monetary standard, 181; on the statistical data available for determining the amount of the precious metals in use as money, &c., 219.
- *Gilbert (G. K.), notes on topographical maps produced by the United State Geological Survey, 747.
- Gilson (Prof. G.), the odoriferous apparatus of the *Blaps mortisaga* (*Coleoptera*), 727.
- Gladstone (Dr. J. H.) on the present methods of teaching chemistry, 78; on the teaching of science in elementary schools, 164; on electrolysis in its physical and chemical bearings, 339.
- and W. Hibbert on the conduction of alloys and solid sulphides, 347; on the electrolysis of thallium trisulphide, 349; on the molecular weight of caoutchouc and other colloids, 640.
- Glaisher (J.) on the circulation of underground waters, 145; on the advisability and possibility of establishing in other parts of the country observations upon the prevalence of earth tremors similar to those now being made in Durham, 522.
- Glazebrook (R. T.) on the desirability of introducing a uniform nomenclature for the fundamental units of mechanics, 27; on standards for use in electrical measurements, 55; on electrolysis in its physical and chemical bearings, 339; *on standards of electrical resistance, 616.
- and T. C. Fitzpatrick on the permanence of the original standards of resistance of the British Association and of other standard coils, 56.
- Glennie (J. S. S.) on the prehistoric race in the Greek islands, 99; Pelasgians, Etruscans, and Iberians: their relations to the founders of the Chaldean and Egyptian civilisations, 857.
- *Gouraud (Col. G. E.), the phonograph, 792.
- Granitoid gneiss or gneissoid granite, the occurrence of a boulder of, in the Halifax hard-bed coal, J. Spencer on, 661; note thereon by Prof. T. G. Bonney, *ib.*
- Grantham (R. B.), on the erosion of the sea-coasts of England and Wales, 898.
- Graphics, comparative, some suggestions for greater uniformity in, by Rev. J. F. Heyes, 769.
- Graphite in the archæan rocks, Rev. A. Irving on the origin of, 679.
- Graphophone, the, by H. Edmunds, 792.
- Gray (T.) on standards for use in electrical measurements, 55; on the earthquake and volcanic phenomena of Japan, 422; on the advisability and possibility of establishing in other parts of the country observations upon the prevalence of earth tremors similar to those now being made in Durham, 522.

- Great oolite, the relations of the, to the forest marble and fuller's-earth in the South-west of England, by H. B. Woodward, 651.
- Grece (Dr. C. J.), the standard, or basis, of taxation, 765.
- Greene (F.) on a photographic image of an electric arc lamp, probably due to phosphorescence in the eye, and on some photographs of an eclipse of the moon, 617.
- Greenhill (A. G.) on the desirability of introducing a uniform nomenclature for the fundamental units of mechanics, 27.
- Gregorian calendar, the general adoption of the, in relation with that of the universal hour, Dr. C. Tondini de Quarenghi on, 747.
- Griffith (G.) on the desirability of introducing a uniform nomenclature for the fundamental units of mechanics, 27.
- Grossmann (Dr. K.) on colour-blindness, 838.
- Haddon (Prof. A. C.) on arrangements for assisting the Marine Biological Association laboratory at Plymouth, 94; on the provincial museums of the United Kingdom, 124; on the occupation of a table at the zoological station at Naples, 150.
- Hale (H.), notes on Rev. E. F. Wilson's report on the Sarcee Indians, 253.
- Haliburton (R. G.) on the North-western tribes of the dominion of Canada, 233; *akkas and dwarfs in Southern Morocco, 745.
- Halliburton (Dr. W. D.) on the physiology of the lymphatic system, 363.
- Hambleton (Dr. G. W.) on the effects of different occupations and employments on the physical development of the human body, 100; notes on chest-types, 849.
- Harcourt (A. G. Vernon) on standards of light, 39; on the present methods of teaching chemistry, 73.
- Harcourt (L. F. Vernon), on the erosion of the sea-coasts of England and Wales, 898.
- Harmonic series of lines, the, in the spectra of the elements, Prof. C. Runge on, 576.
- Harris (W. J.), an examination into the reasons of the price of wheat rising or falling contemporaneously with the variation in the value of foreign currencies, 767.
- Harrison (C.), leasehold enfranchisement, 770.
- Harrison (J. P.), the definition of a nation, 850.
1888.
- Hartley (Prof.) on the action of light on the hydracids of halogens in presence of oxygen, 89; on electrolysis in its physical and chemical bearings, 339.
- Hartog (Prof. M. M.) on the steps taken for establishing a botanical station at Peradeniya, Ceylon, 421; on *adelphotaxy*, an undescribed form of irritability, 702; preliminary note on the functions and homologies of the contractile vacuole in plants and animals, 714.
- Harvie-Brown (J. A.) on the migration of birds, 146.
- Hayward (R. B.) on the desirability of introducing a uniform nomenclature for the fundamental units of mechanics, 27.
- Hazard (Col. R. R.), underground railway communication in great cities, 821.
- Heape (W.) on arrangements for assisting the Marine Biological Association laboratory at Plymouth, 94.
- Hemsley (W. B.), botanical bibliography of the Lesser Antilles, 438.
- Herschel (Prof. A. S.) on the work of the Differential Gravity Meter Committee, 72.
- Heyes (Rev. J. F.) on statigrams, with some suggestions for greater uniformity in comparative graphics, 769.
- Heywood (J.) on the teaching of science in elementary schools, 164.
- Hibbert (W.) and Dr. J. H. Gladstone on the conduction of alloys and solid sulphides, 347; on the electrolysis of thallium trisulphide, 349; on the molecular weight of caoutchouc and other colloids, 640.
- Hicks (Dr. H.) on the prehistoric inhabitants of the British islands, 289; on an ancient sea-beach near Bridlington Quay, 328.
- Hicks (Prof. W. M.) on the desirability of introducing a uniform nomenclature for the fundamental units of mechanics, 27; a vortex analogue of static electricity, 577.
- Higgins (J.), Somersetshire cider, 759.
- Hill (E. J.) on the disengaging of boats, &c., 807.
- Hillhouse (Prof.) on the provincial museums of the United Kingdom, 124.
- Hooker (Sir J. D.) on the desirability of further research in the Antarctic regions, 316.
- Hopkinson (Dr. J.) on standards of light, 39; on standards for use in electrical measurements, 55; on electrolysis in its physical and chemical bearings, 339.
- Hopkinson (J.) on the provincial museums of the United Kingdom, 124;

- on the work of the Corresponding Societies Committee, 255.
- Howarth (O. H.) on the recent volcanic structure of the Azorean Archipelago, 671; the survival of corporal penance, 849.
- Howitt (A. W.), Australian message-sticks and messengers, 842.
- Howorth (H. H.) on the effects of different occupations and employments on the physical development of the human body, 100.
- Hoyle (W. E.) *on the fauna of the Firth of Clyde, 717; *on a deep-sea tow net, *ib.*
- Hughes (Prof. T. McK.) on the erratic blocks of England, Wales, and Ireland, 101.
- Hull (Prof. E.) on the circulation of underground waters, 145; on the advisability and possibility of establishing in other parts of the country observations upon the prevalence of earth tremors similar to those now being made in Durham, 522.
- Human bones discovered by Gen. Pitt-Rivers at Woodcuts, Rotherley, &c., Dr. Beddoe on, 839.
- Human remains from Wiltshire, by Dr. J. G. Garson, 839.
- Hunt (Dr. T. S.) on the study of mineralogy, 627; the theory of solution, 636; mineralogical evolution, 682.
- Hurricanes, modern views about, as compared with the older theories, by Hon. R. Abercromby, 586.
- Huxley (Prof.) on the desirability of further research in the Antarctic regions, 316.
- Hydracids of halogens, the action of light on the, in presence of oxygen, report on, 89.
- Hydrogen and chlorine bulbs, on photographing, by aid of the flash of light which caused their explosion, by Prof. P. P. Bedson, 633.
- *Hydrostatic balance, J. Joly on a, 564.
- Hyksôs, the, or shepherd-kings of Egypt, notes on, by Rev. H. G. Tomkins, 856.
- Iberians, Pelasgians, and Etruscans: their relations to the founders of the Chaldean and Egyptian civilisations, by J. S. S. Glennie, 857.
- Ichthyosaurus*, an, from Mombasa, East Africa, Prof. H. G. Seeley on, with observations on the vertebral characters of the genus, 677.
- Igneous succession in Shropshire, an, by W. W. Watts, 685.
- Impedance of conductors to Leyden-jar discharges, Prof. O. J. Lodge on the, 567.
- Index-number, an official, memorandum on, 186.
- Index-numbers, the accuracy of the proposed calculation of, memorandum on, by Prof. F. Y. Edgeworth, 188.
- as illustrating the progressive exports of British produce and manufactures, by S. Bourne, 536.
- *India, a new route from, to Tibet, by Capt. W. J. Elwes, 741.
- Indian exports, the effects on, of the fall in the gold price of silver, by L. C. Probyn, 768.
- *Industrial education, the, of women abroad and at home, by E. J. Watherston, 771.
- Industrial statistics, by W. Botly, 760.
- Initial meridian for the universal hour, a suggestion from the Bologna Academy of Science towards an agreement on the, by Dr. C. Tondini de Quarenghi, 618.
- International standards, proposed, to control the analysis of iron and steel, by Prof. J. W. Langley, 640.
- Iolite, the occurrence of, in the granite of co. Dublin, J. Joly on, 685.
- Irishwomen's industries, by Miss H. Blackburn, 772.
- Iron and coal industries, the effect of mining royalties on the, Prof. W. R. Sorley on, 755.
- Irving (Rev. A.) on dissociation, 630; chemistry as a school subject, 634; note on the relation of the percentage of carbonic acid in the atmosphere to the life and growth of plants, 661; on the origin of graphite in the archæan rocks, with a review of the alleged evidence of life on the earth in archæan time, 679.
- Isomeric naphthalene derivatives, third report on, 96.
- Jamieson (Prof. A.), the old Orkney click mill, 807.
- Janssen (Dr. J.) sur l'application de l'analyse spectrale à la mécanique moléculaire et sur les spectres de l'oxygène, 547; analyse chronométrique des phénomènes électriques lumineux, 615.
- Japan, the earthquake and volcanic phenomena of, eighth report on, 422.
- , the recent magnetic survey of, Prof. C. G. Knott on, 588.
- Jefferies (O. W.) on local geological photography, 653.
- Jerusalem: Nehemiah's Wall and the royal sepulchres, by G. St. Clair, 744.
- Jevons' method of ascertaining the number of coins in circulation, Prof. F. Y. Edgeworth on, 224.

- Johnson (Prof. A.) on promoting tidal observations in Canada, 27.
- *Johnston (H. H.), the Cameroons, 745.
- Johnston-Lavis (Dr. H. J.) on the volcanic phenomena of Vesuvius and its neighbourhood, 320; on the conservation of heat in volcanic chimneys, 666; on a mass containing metallic iron found on Vesuvius, 667; on the occurrence of leucite at Etna, 669.
- and Dr. T. Anderson on the late eruption in the island of Vulcano, 664.
- Joly (J.) *on a hydrostatic balance, 564; on the meldometer, *ib.*; on a diffusion photometer, 578; on reading electrically meteorological instruments distant from the observer, 589; on the formation of crystals of calcium oxide and magnesium oxide in the oxyhydrogen flame, 634; on the temperature at which beryl is decolorised, 684; on the occurrence of iolite in the granite of co. Dublin, 685.
- Jones (Col.) and E. J. Lowe, abnormal ferns, hybrids, and their parents, 713.
- Jones (F.) on the present methods of teaching chemistry, 73.
- Jones (Prof. T. R.) on the fossil phyllopoda of the palæozoic rocks, 173.
- Jordan, recent explorations east of the, by Capt. A. M. Mantell, 743.
- Judd (Prof.) on the advisability and possibility of establishing in other parts of the country observations upon the prevalence of earth tremors similar to those now being made in Durham, 522.
- *Kakongo, through, by Q. E. Dennett, 745.
- Kew corrections for mercury thermometers, some accurate charts of, W. N. Shaw on, 590.
- 'King Orry's grave,' the monument known as, compared with tumuli in Gloucestershire, by Miss A. W. Buckland, 854.
- Kleiber (J.) on the errors of the argument of statistical tables, 618.
- Knott (Prof. C. G.) on the recent magnetic survey of Japan, 588.
- *Lake Bangweolo and Dr. Livingstone, by E. G. Ravenstein, 745.
- Lamb (Prof.) on the desirability of introducing a uniform nomenclature for the fundamental units of mechanics, 27.
- Laminaria bulbosa*, the development of the bulb in, C. A. Barber on, 710.
- Lemplugh (G. W.) on an ancient sea-beach near Bridlington Quay, 328.
- Langley (Prof. J. W.), proposed international standards to control the analysis of iron and steel, 640.
- Lankester (Prof. Ray) on arrangements for assisting the Marine Biological Association laboratory at Plymouth, 94; on the researches on food fishes at the St. Andrews marine laboratory, 141; on the occupation of a table at the zoological station at Naples, 150; on the development of the oviduct and connected structures in certain freshwater teleostei, 338; on the physiology of the lymphatic system, 363.
- Larmor (J.) on the desirability of introducing a uniform nomenclature for the fundamental units of mechanics, 27; on electrolysis in its physical and chemical bearings, 339.
- Laurie (A. P.), the composition of copper-tin alloys, 637.
- Leasehold enfranchisement, by C. Harrison, 770.
- Lebour (Prof. G. A.) on the circulation of underground waters, 145; on the advisability and possibility of establishing in other parts of the country observations upon the prevalence of earth tremors similar to those now being made in Durham, 522.
- Leclanché's cells, comparison of, with Gassner's dry cells, by W. L. Carpenter, 566.
- Leeds (Dr. A. R.) on the bibliography of solution, 54.
- Lefroy (Gen. Sir J. H.) on the best means of comparing and reducing magnetic observations, 28; on the work of the Differential Gravity Meter Committee, 72; on the North-western tribes of the dominion of Canada, 233.
- *Lesseps (F. de), le canal de Panama, 738.
- Lesser Antilles, botanical bibliography of the, by W. B. Hemsley, 438.
- , zoological bibliography of the, by D. Sharp, 438.
- Leucite, the occurrence of, at Etna, Dr. H. J. Johnston-Lavis on, 669.
- Levden-jar discharges, the impedance of conductors to, Prof. O. J. Lodge on, 567.
- Licence proposed to be transferred in aid of local expenditure, R. H. Inglis Palgrave on the distribution of, 764.
- Life on the earth in archæan time, a review of the alleged evidence of, by Rev. A. Irving, 679.
- Light, standards of, fourth report on, 39; photometric comparison of candles, the pentane standard, the new pentane lamp, and the amyl-acetate lamp, 41; incandescent platinum, 47.

- Light, the action of, on the hydracids of halogens in presence of oxygen, report on, 89.
- , —, on water colours, Dr. A. Richardson on, 641.
- Light in an electrolytic liquid, is its velocity influenced by an electric current in the direction of propagation? by Lord Rayleigh, 341.
- Light or road railways, a few arguments in favour of, by T. S. P. W. D'A. Sellon, 794.
- Lightning conductors, discussion on, 591.
- *Lily disease, a, by Prof. H. M. Ward, 702.
- Lister (J. J.) on the natural history of Christmas Island, 708; on some points in the natural history of the coral fungia, 717.
- 'Little Russia,' by E. D. Morgan, 740.
- Liveing (Prof.) and Prof. Dewar on the absorption spectrum of oxygen, 576.
- *Living bodies, the chemical problems presented by, discussion on, 631.
- *Livingstone, Dr., and Lake Bangweolo, by E. G. Ravenstein, 745.
- Lloyd (S.) on an improved canal lift, 797.
- Lobley (J. L.) on the causes of volcanic action, 670.
- Local Government Bill, amendments founded on experience submitted for the, by E. Chadwick, 779.
- *Lockyer (J. N.), the spectra of meteorites compared with the solar spectrum, 576.
- Locusts in Cyprus, S. Brown on, 716.
- Lodge (A.) on the desirability of introducing a uniform nomenclature for the fundamental units of mechanics, 27.
- Lodge (Prof. O. J.) on the desirability of introducing a uniform nomenclature for the fundamental units of mechanics, 27; on standards for use in electrical measurements, 55; on electrolysis in its physical and chemical bearings, 339; on the measurement of the length of electro-magnetic waves, 567; on the impedance of conductors to Leyden-jar discharges, *ib.*
- *Logarithmic law, the, and its connection with the atomic weights, Dr. G. J. Stoney on, 630.
- *Logarithmic law of atomic weights, Dr. G. J. Stoney on the proof of the, 562.
- Long (Prof. J.), agricultural education, 776.
- Longstaff (G. B.), reasons for a quinquennial census, 769.
- Love (A. E. H.), on the oscillations of a rotating liquid spheroid and the genesis of the moon, 562.
- Love (E. J.) on electrolysis in its physical and chemical bearings, 339.
- Lowe (E. J.) on the effects of the weather of 1888 on the animal and vegetable kingdoms, 726.
- and Col. Jones, abnormal ferns, hybrids, and their parents, 713.
- *Lowrie (W.), the measurement of electricity in a house-to-house supply, 814.
- Lubbock (Sir J.) on the teaching of science in elementary schools, 164; on the prehistoric inhabitants of the British islands, 289; on the desirability of further research in the Antarctic regions, 316; *on the instincts of solitary wasps and bees, 706.
- Luray, the caverns of, by Chev. R. E. Reynolds, 662.
- Lymphatic system, the physiology of the, second report on, 363.
- McClintock (Sir L.), on the desirability of further research in the Antarctic regions, 316.
- Macfarlane (Dr.) on the provincial museums of the United Kingdom, 124.
- MacGregor (Prof. J. G.) on promoting tidal observations in Canada, 27; on the desirability of introducing a uniform nomenclature for the fundamental units of mechanics, *ib.*
- McIntosh (Prof.) on the researches on food-fishes at the St. Andrews marine laboratory, 141.
- McKendrick (Prof.) on the researches on food-fishes at the St. Andrews marine laboratory, 141; on the marine biological station at Granton, 319.
- *Mackenzie (Rev. J.), Bechuanaland and the Land of Ophir, 745.
- *Mackinder (H. J.), note on geographical terminology, 746.
- Mackintosh (D.) on the erratic blocks of England, Wales, and Ireland, 101.
- McLaren (Lord) on meteorological observations on Ben Nevis, 49.
- McLeod (Prof. H.) on the bibliography of solution, 54; on the present methods of teaching chemistry, 73; on electrolysis in its physical and chemical bearings, 339.
- Madagascar, the flora of, Rev. R. Baron on, 724.
- Magnetic disturbances at Fort Rae in 1882-83, by Major H. P. Dawson, 31.
- Magnetic observations, fourth report of the Committee for considering the best means of comparing and reducing, 28; results of a comparison between the wind values and declination disturbances at the Kew Observatory, by Prof. Balfour Stewart and W. L.

- Carpenter, *ib.*; magnetic disturbances at Fort Rae in 1882-83, by Major H. P. Dawson, 31.
- Magnetic survey of Japan, the recent, Prof. C. G. Knott on, 588.
- Magnetisation of soft iron bars of various lengths in a uniform magnetic field, A. Tankadaté on the intensity of, 566.
- Main (P. T.), second report on our experimental knowledge of the properties of matter with respect to volume, pressure, temperature, and specific heat, 465.
- Malthusian theory, the, by E. Chadwick, 777.
- Malvern, the crystalline schists of, Dr. C. Callaway on the origin of, 653.
- Malvern Hills, the crystalline axis of the, sketch of the geology of, by Dr. C. Callaway, 654.
- Mammalia, some extinct tertiary the gigantic size of, Prof. A. Gaudly on, 660.
- Mammalian molar teeth, the evolution of the, to and from the tritubercular type, by H. F. Osborn, 660.
- Man (E. H.) on the funeral rites and ceremonies of the Nicobar islanders, 844.
- Manchester ship canal, plant and machinery in use on the, by L. B. Wells, 796.
- Mannesmann process, on rolling seamless tubes from solid bars or ingots by the, by F. Siemens, 804.
- Mantell (Capt. A. M.), recent explorations east of the Jordan, 743.
- 'Manure' gravels of Wexford, second report on the, 133.
- Maps, perspective and common, by A. W. Clayden, 740.
- *—, topographic, produced by the United States Geological Survey, notes on, by G. K. Gilbert, 747.
- Marine Biological Association laboratory at Plymouth, the, report of the Committee for making arrangements for assisting, 94.
- Marine biological station at Granton, Scotland, report of the Committee for aiding in the maintenance of the establishment of a, 319.
- Marriage and descent, the laws of, on a method of investigating, by Dr. E. B. Tylor, 840.
- Marriage customs of the New Britain group, by Rev. B. Danks, 847.
- Marsh (J. E.) *on closed-chain formulæ, 631; *on Van't Hoff's hypothesis and the constitution of benzene, *ib.*
- Marsh (Prof. O. C.), *comparison of the principal forms of *Dinosauria* of Europe and America, 660; restoration of *Brontops robustus*, from the miocene of America, 706.
- Marshall (Prof. A.) on the best method of ascertaining and measuring variations in the value of the monetary standard, 181; on the statistical data available for determining the amount of the precious metals in use as money, &c., 219.
- Marshall (Prof. A. M.) on the provincial museums of the United Kingdom, 124; on the occupation of a table at the zoological station at Naples, 150; on the development of the oviduct and connected structures in certain freshwater teleostei, 338.
- Marten (E. B.) on the circulation of underground waters, 145.
- Martin (J. B.) on the best method of ascertaining and measuring variations in the value of the monetary standard, 181; on the statistical data available for determining the amount of the precious metals in use as money, &c., 219.
- Maskelyne (Prof. N. S.) on the teaching of science in elementary schools, 164.
- Mass, a, containing metallic iron found on Vesuvius, Dr. H. J. Johnston-Lavis on, 667.
- Mathematical and Physical Section, Address by Prof. G. F. Fitzgerald to the, 557.
- Matter, second report on our experimental knowledge of the properties of, with respect to volume, pressure, temperature, and specific heat, 465.
- Mavor (J.) on wage statistics and theories, 757.
- *Maxwell's equations of electromagnetic waves, Prof. H. A. Rowland on a modification of, 617.
- Mécanique moléculaire, sur l'application de l'analyse spectrale à la, par Dr. J. Janssen, 547.
- Mechanical pathology considered in its relation to bridge design, by G. H. Thomson, 793.
- Mechanical Section, Address by W. H. Preece to the, 781.
- Melanesia, social regulations in, by Rev. R. H. Codrington, 843.
- Meidola (Prof. R.) on the present methods of teaching chemistry, 73; on the work of the Corresponding Societies Committee, 255; on the prehistoric inhabitants of the British Islands, 289; on the advisability and possibility of establishing in other parts of the country observations upon the prevalence of earth tremors similar to those now being made in Durham, 522; evidence of the tetravalency of oxygen derived from the constitution of the azonaphthol-compounds, 635.
- Meldometer, J. Joly on the, 564.

- Metal coils, the friction of, by Prof. H. Shaw and E. Shaw, 540.
- *Meteorites, on the mechanical conditions of a swarm of, and on theories of cosmogony, by Prof. G. H. Darwin, 590.
- *—, the spectra of, compared with the solar spectrum, by J. N. Lockyer, 576.
- *Meteorological conditions of the Red Sea, by Lieut.-Gen. Strachey, 738.
- Meteorological instruments distant from the observer, on reading electrically, by J. Joly, 589.
- Meteorological observations on Ben Nevis, report of the Committee for co-operating with the Scottish Meteorological Society in making, 49.
- Microscopic structure of the older rocks of Anglesey, report on the, 367.
- Midford sands, further note on the, by H. B. Woodward, 650.
- Migration of birds, report on the, 146.
- Mill (Dr. H. R.) on arranging an investigation of the seasonal variations of temperature in lakes, rivers, and estuaries, 326; on the temperature of some Scottish rivers, 588; the salinity of the Clyde Sea area, 738; sea temperatures on the continental shelf, 739.
- Miller (J. B.) and Dr. W. Bott, further researches on the pyrocresols, 642.
- Milne (Prof. J.) on the earthquake and volcanic phenomena of Japan, 422.
- Milne-Home (Mr.) on meteorological observations on Ben Nevis, 49.
- Mineral and thermal waters, British, a list of works referring to, by W. H. Dalton, 859.
- Mineralogical evolution, by Dr. T. S. Hunt, 682.
- Mineralogy, the study of, Dr. T. S. Hunt on, 627.
- Miners' electric safety-lamps, by N. Watts, 816.
- Mining royalties and their effect on the iron and coal industries, Prof. W. R. Sorley on, 755.
- Molecular weight of caoutchouc and other colloids, Dr. J. H. Gladstone and W. Hibbert on the, 640.
- Monetary standard, the, variations in the value of, second report on the best method of ascertaining and measuring, 181; memorandum on an official index-number, 186; memorandum by Prof. F. Y. Edgeworth on the accuracy of the proposed calculation of index-numbers, 188.
- Moon, on the genesis of the, and the oscillations of a rotating liquid spheroid, by A. E. H. Love, 562.
- , some photographs of an eclipse of the, F. Greene on, 617.
- More (A. G.) on the migration of birds, 146.
- Morgan (E. D.), 'Little Russia,' 740; *Russian topographical surveys, 741.
- *Morocco, Southern, akkas and dwarfs in, by R. G. Haliburton, 745.
- Mortar, the ancient Roman, from the London Wall, the composition of, by J. Spiller, 637.
- Morton (G. H.) on the circulation of underground waters, 145.
- Moseley (Prof.) on arrangements for assisting the Marine Biological Association laboratory at Plymouth, 94; on the occupation of a table at the zoological station at Naples, 150; on the desirability of further research in the Antarctic regions, 316.
- Mott (F. T.) on the provincial museums of the United Kingdom, 124.
- Muir (Dr.) on the desirability of introducing a uniform nomenclature for the fundamental units of mechanics, 27.
- Muir (P.) on the present methods of teaching chemistry, 73.
- Muirhead (Dr. A.) on standards for use in electrical measurements, 55.
- Muirhead (Dr. H.) on the effects of different occupations and employments on the physical development of the human body, 100; on the prehistoric inhabitants of the British islands, 289.
- Mulhall (M. G.), the growth of American industries and wealth, 757.
- Munro (Dr. R.) on the prehistoric inhabitants of the British islands, 289.
- Murray (G. M.) on the flora of the Bahamas, 361.
- Murray (Dr. J.) on meteorological observations on Ben Nevis, 49; on the desirability of further research in the Antarctic regions, 316; on the marine biological station at Granton, 319; on arranging an investigation of the seasonal variations of temperature in lakes, rivers, and estuaries, 326.
- Nares (Capt. Sir G.) on the desirability of further research in the Antarctic regions, 316; on the erosion of the sea-coasts of England and Wales, 898.
- Nation, the definition of a, by J. P. Harrison, 850.
- Necklaces in relation to prehistoric commerce, by Miss A. W. Buckland, 849.
- Nehemiah's wall and the royal sepulchres, by G. St. Clair, 744.
- *Nepenthes, the morphology of the pitcher of, Prof. Bower on, 702.
- New Britain group, marriage customs of the, by Rev. B. Danks, 847.
- Newberry (P. E.) on the plant-remains discovered by Mr. W. M. Flinders

- Petrie in the cemetery of Hawara, Lower Egypt, 712.
- Newton (Prof. A.) on the migration of birds, 146; on the present state of our knowledge of the zoology and botany of the West India islands, and on the steps taken to investigate ascertained deficiencies in the fauna and flora, 437; on the irruption of *Syrrhaptes paradoxus*, 703.
- Nicholson (Prof. J. S.) on the best methods of ascertaining and measuring variations in the value of the monetary standard, 181; on the statistical data available for determining the amount of the precious metals in use as money, &c., 219.
- Nicobar islanders, the funeral rites and ceremonies of the, E. H. Man on, 844.
- Nicol (Dr. W. W. J.) on the bibliography of solution, 54; on the nature of solution, 93; a new gas analysis apparatus, 632.
- Nile, the region from the, to the Euphrates, notes on the geography of, as known to the ancient Egyptians, by Rev. H. G. Tomkins, 741; remarks thereon by Major Conder, 743.
- Nile flood, the Raiyān project for the storage of, by Cope Whitehouse, 799.
- Niven (Prof. C.) on the work of the Differential Gravity Meter Committee, 72.
- Norfolk (F.), *the vital and commercial statistics of Bath, 780; *old age and sickness assurance for the mercantile and professional classes, *ib.*
- North-western tribes of the dominion of Canada, fourth report on the physical characters, languages, and industrial and social condition of the, 233; report on the Sarcee Indians, by Rev. E. F. Wilson, 242; notes thereon by H. Hale, 253.
- *Nutrition of embryos, certain adaptations for the, F. W. Oliver on, 710.
- Observations made in the anthropometric laboratory at Manchester, by G. W. Bloxam and Dr. J. G. Garson, 854.
- Occupations and employments, different, the effects of, on the physical development of the human body, report on, 100.
- Ohm's law in electrolytes, Prof. Fitzgerald and F. Trouton on the accuracy of, 341.
- Older rocks of Anglesey, report on the microscopic structure of the, 367.
- Oligoclase, three specimens of, from North Carolina, exhibiting curious optical properties, Dr. P. Frazer on, 655.
- Oliver (Prof.) on our present knowledge of the flora of China, 420.
- *Oliver (F. W.) on certain adaptations for the nutrition of embryos, 710.
- Ommanney (Adm. Sir E.), on the desirability of further research in the Antarctic regions, 316; on the erosion of the sea-coasts of England and Wales, 898.
- Oolitic texture in limestone rocks, Prof. H. G. Seeley on the origin of, 674.
- *Ophir, the Land of, and Bechuanaland, by Rev. J. Mackenzie, 745.
- Orbits, catenaries, and curved rays, Prof. J. D. Everett on the relations between, 581.
- *Ordnance Survey, photographic and photozincographic processes employed in the, by Col. J. H. Bolland, 746.
- Orkney click mill, the old, by Prof. A. Jamieson, 807.
- Osborn (H. F.), the evolution of the mammalian molar teeth to and from the tritubercular type, 660.
- Oviduct, the, and connected structures in certain fresh-water teleostei, report on the development of, 338.
- Oxygen, evidence of the tetravalency of, derived from the constitution of the azonaphthol-compounds, by Prof. R. Meldola, 635.
- , the absorption spectrum of, Profs. Liveing and Dewar on, 576.
- , the atomic weight of, Dr. A. Scott on, 631.
- Oxygène, les spectres de l', Dr. J. Janssen sur, 547.
- Pachytheca*, a silurian alga of doubtful affinities, C. A. Barber on, 711.
- *Pahang, an independent state in the Malayan peninsula, W. B. d'Almeida on, 747.
- Palgrave (R. H. Inglis) on the best method of ascertaining and measuring variations in the value of the monetary standard, 181; on the statistical data available for determining the amount of the precious metals in use as money, &c., 219; on the distribution of the licences proposed to be transferred in aid of local expenditure, 764.
- *Panama, le canal de, by F. de Lesseps, 738.
- Parsons (Capt. J.) on the erosion of the sea-coasts of England and Wales, 898.
- Paterson (Dr. A. M.) on the effects of different occupations and employments on the physical development of the human body, 100.
- Pearse (J. W.), transmission of motion and power, 823.

- Pelasgians, Etruscans, and Iberians : their relations to the founders of the Chaldean and Egyptian civilisations, by J. S. S. Glennie, 857.
- Pengelly (W.) on the prehistoric race in the Greek islands, 99 ; on the erratic blocks of England, Wales, and Ireland, 101 ; on the circulation of underground waters, 145 ; on the prehistoric inhabitants of the British islands, 289.
- Peradeniya, Ceylon, second report on the steps taken for establishing a botanical station at, 421.
- Permanence of the original standards of resistance of the British Association and of other standard coils, R. T. Glazebrook and T. C. Fitzpatrick on the, 56.
- Perry (Prof. J.) on standards for use in electrical measurements, 55.
- * — and Profs. Sir W. Thomson and Ayrton, electrometric determination of 'v,' 616.
- Perry (Prof. S. J.) on the best means of comparing and reducing magnetic observations, 28.
- Petrie, Mr. W. M. Flinders, the plant remains discovered by, in the cemetery of Hawara, Lower Egypt, P. E. Newberry on, 712.
- Phénomènes électriques lumineux, analyse chronométrique des, par Dr. J. Janssen, 615.
- *Phonograph, the, by Col. G. E. Gouraud, 792.
- *Photographic and photozincographic processes employed in the Ordnance Survey, by Col. J. H. Bolland, 746.
- Photographic image of an electric arc lamp, a, probably due to phosphorescence in the eye, F. Greene on, 617.
- Photographing hydrogen and chlorine bulbs by aid of the flash of light which caused their explosion, Prof. P. P. Bedson on, 633.
- Photography, local geological, O. W. Jeffs on, 653.
- Photometer, a diffusion, J. Joly on, 578.
- Phyllopora, the fossil, of the palæozoic rocks, sixth report on, 173.
- Physical Section, the Mathematical and, Address by Prof. G. F. Fitzgerald to, 557.
- Physiology of the lymphatic* system, second report on the, 363.
- Pickering (Prof.) on the bibliography of solution, 54.
- Pidgeon (W. R.), the Shipman engine, 806.
- Pitman (E.), economy in education and in writing, 776.
- Pitt-Rivers (Lieut.-Gen.) on the effects of different occupations and employments on the physical development of the human body, 100 ; on the work of the Corresponding Societies Committee, 255 ; Address to the Anthropological Section by, 825.
- Pitt-Rivers, Lieut.-Gen., human bones discovered by, at Woodcuts, Rotherley, &c., Dr. Beddoe on, 839.
- Plant (J.) on the erratic blocks of England, Wales, and Ireland, 101 ; on the circulation of underground waters, 145.
- Plant and machinery in use on the Manchester ship canal, by L. B. Wells, 796.
- Plant remains discovered by Mr. W. M. Flinders Petrie in the cemetery of Hawara, Lower Egypt, P. E. Newberry on the, 712.
- Plants, the life and growth of, the relation of the percentage of carbonic acid in the atmosphere to, Rev. A. Irving on, 661.
- Playfair (Col. Sir L.), Tunis since the French protectorate, 745.
- Polarisation of small electrodes in dilute sulphuric acid, Dr. F. Richarz on the, 350.
- Portland sands, the, of Swindon and elsewhere, note on, by H. B. Woodward, 652.
- *Poulton (E. B.), heredity in cats with an extra number of toes, 707.
- Poynting (Prof. J. H.) on the desirability of introducing a uniform nomenclature for the fundamental units of mechanics, 27 ; on the work of the Differential Gravity Meter Committee, 72 ; on electrolysis in its physical and chemical bearings, 339.
- Precious metals, the amount of the, in use as money in the principal countries, the chief forms in which the money is employed, and the amount annually used in the arts, report as to the statistical data available for determining, 219 ; memorandum, by Prof. F. Y. Edgeworth, on Jevons' method of ascertaining the number of coins in circulation, 224.
- Preece (W. H.) on standards of light, 39 ; on standards for use in electrical measurements, 55 ; on the C.G.S. units of measurement, 616 ; Address to the Mechanical Section by, 781.
- Prehistoric inhabitants of the British Islands, the localities in which evidences of the existence of, are found, second report of the Committee for ascertaining and recording, 289.
- Prehistoric race in the Greek islands, third report on the, 99.
- Prestwich (Prof. J.) on the erratic blocks of England, Wales, and Ireland, 101 ; on the circulation of underground waters, 145 ; on the advisability and possibility of establishing in other parts of the country observations upon

- the prevalence of earth tremors similar to those now being made in Durham, 522; on the erosion of the sea-coasts of England and Wales, 898.
- Price (L. L.), the relations between sliding scales and economic theory, 523.
- Probyn (L. C.), the effects on Indian exports of the fall in the gold price of silver, 768.
- Provincial museums of the United Kingdom, further report on the, 124.
- Pyrocresols, further researches on the, by Dr. W. Bott and J. B. Miller, 642.
- Quartz, a specimen of, from Australia, exhibiting curious optical properties, Dr. P. Frazer on, 655.
- Quinquennial census, reasons for a, by G. B. Longstaff, 769.
- Raian and Fayum basins, the, by Cope Whitehouse, 746.
- Railway communication; underground, in great cities, by Col. R. R. Hazard, 821.
- Railways, light or road, a few arguments in favour of, by T. S. P. W. D'A. Sellon, 794.
- Raiyān project for the storage of Nile flood, the, by Cope Whitehouse, 799.
- Ramsay (Prof. W.) on the bibliography of solution, 54; on the nature of solution, 93; on electrolysis in its physical and chemical bearings, 339; *on the behaviour of water under great provocation from heat, 562.
- *Ravenstein (E. G.), Dr. Livingstone and Lake Bangweolo, 745.
- Rawson (Sir R.) on the effects of different occupations and employments on the physical development of the human body, 100; on the work of the Corresponding Societies Committee, 255.
- Rayleigh (Prof. Lord) on standards of light, 39; on standards for use in electrical measurements, 55; on electrolysis in its physical and chemical bearings, 339; is the velocity of light in an electrolytic liquid influenced by an electric current in the direction of propagation? 341.
- Recurring decimals and Fermat's theorem, Prof. R. W. Genese on, 580.
- *Red Sea, meteorological conditions of the, by Lieut.-Gen. Strachey, 738.
- Redman (J. B.) on the erosion of the sea-coasts of England and Wales, 898.
- Rees (W. L.), associative economics applied to colonisation, 752.
- Reid (C.) on an ancient sea-beach near Bridlington Quay, 328.
- Reid (C.) and H. N. Ridley, fossil arctic plants from the lacustrine deposit at Hoxne, in Suffolk, 674.
- Reinold (Prof.) on electrolysis in its physical and chemical bearings, 339.
- Revenue system of the United States, the, by Dr. A. Shaw, 763.
- Revolving sails, or air-propellers, by H. C. Vogt, 820.
- Reynolds (Prof. J. E.) on some new silicon compounds, 640; on some new thiocarbamide compounds, *ib.*
- Reynolds (Chev. R. E.), the caverns of Luray, 662; notes on the shell-mounds and ossuaries of the Choptank river, Maryland, U.S.A., 845.
- Richards (Adm. Sir G. H.) on the desirability of further research in the Antarctic regions, 316.
- Richardson (Dr. A.) on the action of light on the hydracids of halogens in presence of oxygen, 89; on the action of light on water colours, 641.
- Richarz (Dr. F.) on the polarisation of small electrodes in dilute sulphuric acid, 350.
- Ricketts (Dr. C.) on a probable cause of contortions of strata, 684.
- Ridley (H. N.) and C. Reid, fossil arctic plants from the lacustrine deposit at Hoxne, in Suffolk, 674.
- River of Joseph, the, the Fayum and Raian basins, by Cope Whitehouse, 746.
- Roberts (C.) on the effects of different occupations and employments on the physical development of the human body, 100.
- Roberts (I.) on the circulation of underground waters, 145; on arranging an investigation of the seasonal variations of temperature in lakes, rivers, and estuaries, 326; on the advisability and possibility of establishing in other parts of the country observations upon the prevalence of earth tremors similar to those now being made in Durham, 522.
- Roberts-Austen (Prof. W. C.) on the influence of silicon on the properties of steel, 69; on electrolysis in its physical and chemical bearings, 339.
- Roscoe (Sir H. E.) on the teaching of science in elementary schools, 164.
- Rotating liquid spheroid, on the oscillations of a, and the genesis of the moon, by A. E. H. Love, 562.
- *Rotation of a dynamo, on controlling the direction of, by A. Winter, 824.
- Rowland (Prof. H. A.), *recent progress in the use of concave gratings for spectrum analysis, 566; *on a modification of Maxwell's equations of electromagnetic waves, 617.

- Roy (Prof.) and J. G. Adami on the physiological bearing of waist-belts and stays, 704.
- Rücker (Prof.) on electrolysis in its physical and chemical bearings, 339.
- Rudler (F. W.) on the prehistoric race in the Greek islands, 99; on the effects of different occupations and employments on the physical development of the human body, 100; on the volcanic phenomena of Vesuvius and its neighbourhood, 320.
- Runge (Prof. C.) on the harmonic series of lines in the spectra of the elements, 576.
- Russell (Dr. W. J.) on the present methods of teaching chemistry, 73; on the action of light on the hydracids of halogens in presence of oxygen, 89.
- *Russian topographical surveys, by E. D. Morgan, 741.
- St. Clair (G.), Jerusalem: Nehemiah's wall and the royal sepulchres, 744; totem clans and star worship, 848.
- Salinity of the Clyde sea area, the, by Dr. H. R. Mill, 738.
- Sanderson (Prof. B.) on the researches on food-fishes at the St. Andrews marine laboratory, 141.
- Sarcee Indians, report on the, by Rev. E. F. Wilson, 242; notes thereon, by H. Hale, 253.
- Schäfer (Prof.) on the physiology of the lymphatic system, 363.
- Schuster (Prof. A.) on the best means of comparing and reducing magnetic observations, 28; on standards of light, 39; on standards for use in electrical measurements, 55; on the work of the Differential Gravity Meter Committee, 72; on electrolysis in its physical and chemical bearings, 339.
- Science, the teaching of, in elementary schools, report on, 164.
- Sclater (Dr. P. L.) on arrangements for assisting the Marine Biological Association laboratory at Plymouth, 94; on the occupation of a table at the zoological station at Naples, 150; on the desirability of further research in the Antarctic regions, 316; on the present state of our knowledge of the zoology and botany of the West India islands, and on the steps taken to investigate ascertained deficiencies in the fauna and flora, 437.
- Scott (Dr. A.) on the atomic weight of oxygen, 631.
- Scottish rivers, on the temperature of some, by Dr. H. R. Mill, 588.
- Sea of Bengal, the echinodermata of the, Prof. F. J. Bell on, 718.
- *Sea temperatures in the neighbourhood of Cape Guardafui, by Lieut.-Gen. Strachey, 738.
- Sea temperatures of the continental shelf, by Dr. H. R. Mill, 739.
- Sea-beach, an ancient, near Bridlington Quay, report on, 328.
- Seamless tubes from solid bars or ingots, rolling, by the Mannesmann process, F. Siemens on, 804.
- Seasonal variations of temperature in lakes, rivers, and estuaries in various parts of the United Kingdom, report of the Committee for arranging an investigation of the, in co-operation with the local societies represented on the Association, 326.
- Sedgwick (A.) on arrangements for assisting the Marine Biological Association laboratory at Plymouth, 94; on the occupation of a table at the zoological station at Naples, 150; on the development of the oviduct and connected structures in certain fresh-water teleostei, 338.
- Seeley (Prof. H. G.) on the origin of oolitic texture in limestone rocks, 674; on an *ichthyosaurus* from Mombasa, East Africa, with observations on the vertebral characters of the genus, 677.
- Seismograph, an improved, by E. A. Cowper, 818.
- Sellon (R. P.), electric light applied to night navigation upon the Suez Canal, 814.
- Sellon (T. S. P. W. D'A.), a few arguments in favour of light or road railways, 794.
- Sensation, composition of, and notion of space, L. de la Rive on, 585.
- Severn watershed, the, by J. W. W. Bund, 799.
- Sharp (D.), zoological bibliography of the Lesser Antilles, 438.
- Shaw (Dr. A.), the revenue system of the United States, 763.
- Shaw (E.) and Prof. H. Shaw, the friction of metal coils, 540.
- Shaw (G. B.), the transition to social democracy, 761.
- Shaw (Prof. H.), a new sphere planimeter, 584.
- and E. Shaw, the friction of metal coils, 540.
- Shaw (W. N.) on the desirability of introducing a uniform nomenclature for the fundamental units of mechanics, 27; on standards for use in electrical measurements, 55; on electrolysis in its physical and chemical bearings, 339; on some accurate charts of Kew corrections for mercury thermometers, 590; on an apparatus for determining temperature by the variation of electrical resistance, *ib.*

- Shell-mounds and ossuaries of the Choptank river, Maryland, U.S.A., notes on the, by Chev. R. E. Reynolds, 845.
- Shenstone (W. A.) on the present methods of teaching chemistry, 73.
- Shipman engine, the, by W. R. Pidgeon, 806.
- Shore (T. W.), beds exposed in the Southampton new dock excavation, 672; Celtic earthworks in Hampshire, in reference to the density of the Celtic population, 852.
- Sicilies, the Two, the volcanoes of, by Dr. T. Anderson, 663.
- Sidgwick (Prof. H.) on the best method of ascertaining and measuring variations in the value of the monetary standard, 181; an analysis of the current conception of State socialism, 760.
- Siemens (F.) on rolling seamless tubes from solid bars or ingots by the Mannesmann process, 804.
- Silicon, the influence of, on the properties of steel, second report on, 69.
- Silicon compounds, some new, Prof. J. E. Reynolds on, 640.
- Sladen (P.) on arrangements for assisting the Marine Biological Association laboratory at Plymouth, 94; on the occupation of a table at the zoological station at Naples, 150.
- Sliding scales and economic theory, the relations between, by L. L. Price, 523.
- Sloan (A. D.) on the occupation of the table at the zoological station at Naples, 153.
- Smith (H. W.) and Prof. H. B. Dixon, the incompleteness of combustion in explosions, 632.
- Smithells (Prof.) on the present methods of teaching chemistry, 73.
- Social democracy, the transition to, by G. B. Shaw, 761.
- Social regulations in Melanesia, by Rev. R. H. Codrington, 843.
- Socialism, State, an analysis of the current conception of, by Prof. H. Sidgwick, 760.
- *Solar spectrum, the spectra of meteorites compared with the, by J. N. Lockyer, 576.
- Solution, the bibliography of, second report on, 54.
- , the nature of, second report on, 93.
- , the theory of, by Dr. T. S. Hunt, 636.
- Solution of copper in acids, the rate of, V. H. Veley on, 638.
- Somerset, some points of interest in the geology of, by W. A. E. Ussher, 659.
- *Somersetshire cider, by J. Higgins, 759.
- Sorley (Prof. W. R.) on mining royalties and their effect on the iron and coal industries, 755.
- Southampton new dock excavation, beds exposed in the, by T. W. Shore, 672.
- Space, notion of, and composition of sensation, L. de la Rive on, 585.
- *Spectra of meteorites, the, compared with the solar spectrum, by J. N. Lockyer, 576.
- Spectra of the elements, the harmonic series of lines in the, Prof. C. Runge on, 576.
- Spectres de l'oxygène, Dr. J. Janssen sur les, 547.
- *Spectrum analysis, recent progress in the use of concave gratings for, by Prof. H. A. Rowland, 566.
- Spencer (J.) on the occurrence of a boulder of granitoid gneiss or gneissoid granite in the Halifax hard-bed coal, 661.
- Sphere planimeter, a new, by Prof. H. Shaw, 584.
- Spiller (J.), the composition of the ancient Roman mortar from the London Wall, 637.
- Stallard (Mr.) on the present methods of teaching chemistry, 73.
- Star worship, totem clans and, by G. St. Clair, 848.
- State socialism, an analysis of the current conception of, by Prof. H. Sidgwick, 760.
- Static electricity, a vortex analogue of, by Prof. W. M. Hicks, 577.
- Statigrams, Rev. J. F. Heyes on, with some suggestions for greater uniformity in comparative graphics, 769.
- Statistical tables, the errors of the argument of, J. Kleiber on, 618.
- Statistics, agricultural, commercial, industrial, and banking, by W. Botly, 760.
- , Economic Science and, Address by Lord Bramwell to the Section of, 749.
- *—, the vital and commercial, of Bath, by F. Norfolk, 780.
- Statistics of examination, Prof. F. Y. Edgeworth on the, 763.
- Stays and waist-belts, the physiological bearing of, Prof. Roy and J. G. Adami on, 704.
- Steam at high pressures, the efficiency of, and the Carnot theorem, by W. W. Beaumont, 820.
- Steam engine diagrams, by M. F. Fitzgerald, 819.
- Steel, the influence of silicon on the properties of, second report on, 69.
- Steward (Rev. J. J.) on arranging an investigation of the seasonal variations of temperature in lakes, rivers, and estuaries, 326.
- Stewart (Prof. Balfour) on the best means of comparing and reducing magnetic observations, 28.

- Stewart (Prof. Balfour) and W. L. Carpenter, results of a comparison between the wind values and declination disturbances at the Kew Observatory, 28.
- Stirling (Prof.) on the researches on food-fishes at the St. Andrews marine laboratory, 141.
- Stone (J. H.), the ancient inhabitants of the Canary Islands, 851.
- Stoney (Dr. G. J.) on the desirability of introducing a uniform nomenclature for the fundamental units of mechanics, 27; *on the proof of the logarithmic law of atomic weights, 562; *on the logarithmic law and its connection with the atomic weights, 630.
- Stooke (T. S.) on the circulation of underground waters, 145.
- Strachey (Lieut.-Gen. R.) on the work of the Differential Gravity Meter Committee, 72; on the desirability of further research in the Antarctic regions, 316; *meteorological conditions of the Red Sea, 738; *sea temperatures in the neighbourhood of Cape Guardafui, *ib.*
- Stretching of liquids, Prof. A. M. Worthington on the, 583.
- Stroud (Prof. W.) and W. W. H. Gee, electro-calorimetry, 565.
- Sun-myths in modern Hellas, by J. T. Bent, 850.
- Surtees (Capt. C.), mission to El-Wedj, 747.
- Swan (J. W.) on an automatic fire-damp detector, 817.
- Swiss, the physique of the, as influenced by race and by media, by Dr. Beddoe, 837.
- Symons (G. J.) on the circulation of underground waters, 145; on the work of the Corresponding Societies Committee, 255; on the advisability and possibility of establishing in other parts of the country observations upon the prevalence of earth tremors similar to those now being made in Durham, 522.
- Syrrhaptus paradoxus*, the irruption of, Prof. Newton on, 703.
- Tanakadaté (A.) on the intensity of magnetisation of soft iron bars of various lengths in a uniform magnetic field, 566.
- Tanner (R. R.), the suitability of small towns for factory industries, 767.
- Taxation, the standard, or basis, of, by Dr. C. J. Grece, 765.
- *Taylor (G.), Formosa: characteristic traits of the island and its aboriginal inhabitants, 747.
- Taylor (H.) on standards for use in electrical measurements, 55.
- Teall (J. J. H.) on the volcanic phenomena of Vesuvius and its neighbourhood, 320; on the microscopic structure of the older rocks of Anglesey, 367.
- Teleostean ova, some, and their development, J. T. Cunningham on, 703.
- Teleostei, certain fresh-water, report on the development of the oviduct and connected structures in, 338.
- Temperature, an apparatus for determining, by the variation of electrical resistance, W. N. Shaw on, 590.
- Temperature of some Scottish rivers, Dr. H. R. Mill on the, 588.
- Temple (Sir R.) on the teaching of science in elementary schools, 164.
- Tetravalency of oxygen, evidence of the, derived from the constitution of the azonaphthol-compounds, by Prof. R. Meldola, 635.
- Thallium trisulphide, the electrolysis of, Dr. J. H. Gladstone and W. Hibbert on, 349.
- Thermal and mineral waters, British, a list of works referring to, by W. H. Dalton, 859.
- Thermometers, mercury, some accurate charts of Kew corrections for, W. N. Shaw on, 590.
- Thiocarbamide compounds, some new, Prof. J. E. Reynolds on, 640.
- Thiselton-Dyer (W. T.) on the flora of the Bahamas, 361; on our present knowledge of the flora of China, 420; on the steps taken for establishing a botanical station at Peradeniya, Ceylon, 421; on the present state of our knowledge of the zoology and botany of the West India Islands, and on the steps taken to investigate ascertained deficiencies in the fauna and flora, 437; Address to the Biological Section by, 686.
- Thompson (Prof. S. P.) on electrolysis in its physical and chemical bearings, 339.
- Thomson (G. H.), mechanical pathology considered in its relation to bridge design, 793.
- Thomson (Prof. J.) on flux and reflux of water in open channels or in pipes or other ducts, 574.
- Thomson (Prof. J. J.) on standards for use in electrical measurements, 55; on electrolysis in its physical and chemical bearings, 339.
- Thomson (J. M.) on electrolysis in its physical and chemical bearings, 339.
- *Thomson (Jos.), notes from the Atlas Mountains, 745.
- Thomson (Prof. Sir W.) on the best means of comparing and reducing

- magnetic observations, 28; on standards for use in electrical measurements, 55; on the work of the Differential Gravity Meter Committee, 72; on the desirability of further research in the Antarctic regions, 316; on electrolysis in its physical and chemical bearings, 339; a simple hypothesis for electro-magnetic induction of incomplete circuits, with consequent equations of electric motion in fixed homogeneous or heterogeneous solid matter, 567; on the transference of electricity within a homogeneous solid conductor, 570; five applications of Fourier's law of diffusion, illustrated by a diagram of curves with absolute numerical values, 571.
- *Thomson (Prof. Sir W.) and Profs. Ayrton and Perry, electrometric determination of 'v,' 616.
- *Tibet, a new route from India to, by Capt. W. J. Elwes, 741.
- Tidal observations in Canada, fourth report of the Committee for promoting, 27.
- Tiddeman (R. H.) on the erratic blocks of England, Wales, and Ireland, 101.
- Tilden (Prof. W. A.) on the bibliography of solution, 54; on the influence of silicon on the properties of steel, 69; on the nature of solution, 93; on isomeric naphthalene derivatives, 96; on electrolysis in its physical and chemical bearings, 339; Address to the Chemical Section by, 620.
- Tomkins (Rev. H. G.), notes on the geography of the region from the Nile to the Euphrates, as known to the ancient Egyptians, 741; some account of the ancient (præ-Roman) stronghold of Worlebury, near Weston-super-Mare, 851; notes on the Hyksôs or shepherd-kings of Egypt, 856.
- Tomlinson (H.) on standards for use in electrical measurements, 55.
- Tondini de Quarenghi (Dr. C.), a suggestion from the Bologna Academy of Science towards an agreement on the initial meridian for the universal hour, 618; on the general adoption of the Gregorian calendar in relation with that of the universal hour, 747.
- Topley (W.) on the circulation of underground waters, 145; on the work of the Corresponding Societies Committee, 255; on the erosion of the sea-coasts of England and Wales, 898.
- Totem clans and star worship, by G. St. Clair, 848.
- Traill (Dr. A.) on the burning by lightning of a magnet on a generating dynamo, 615.
- Transmission of motion and power, by J. W. Pearse, 823.
- *Transvaal, the, or South African Republic, by P. H. Ford, 745.
- Traquair (Dr.) on the provincial museums of the United Kingdom, 124; on the researches on food-fishes at the St. Andrews marine laboratory, 141.
- Trimen (Dr.) on the steps taken for establishing a botanical station at Peradeniya, Ceylon, 421.
- Trouton (F.) and Prof. Fitzgerald on the accuracy of Ohm's law in electrolytes, 341.
- *Tubificidæ, contributions to the anatomy of the, by F. E. Beddard, 723.
- Tunis since the French protectorate, by Col. Sir L. Playfair, 745.
- Turner (T.) on the influence of silicon on the properties of steel, 69.
- Twenty-ton travelling crane, the application of electricity to the working of a, by W. Anderson, 808.
- Tylden-Wright (Mr.) on the circulation of underground waters, 145.
- Tylor (Dr. E. B.) on the North-western tribes of the dominion of Canada, 233; on a method of investigating the development of institutions, applied to laws of marriage and descent, 840.
- Tytherington and Thornbury section, Rev. H. H. Winwood on the, 658.
- Underground railway communication in great cities, by Col. R. R. Hazard, 821.
- Underground waters in the permeable formations of England and Wales, the circulation of, and the quantity and character of the water supplied to various towns and districts from these formations, fourteenth report on the, 145.
- Underground waters of the permeable formations of England, the replenishment of the, J. B. Denton on, 797.
- Uniform nomenclature for the fundamental units of mechanics, report of the Committee for considering the desirability of introducing a, and for co-operating with other bodies engaged in similar work, 27.
- United States, the revenue system of the, by Dr. A. Shaw, 763.
- Universal hour, the general adoption of the Gregorian calendar in relation with that of the, Dr. C. Tondini de Quarenghi on, 747.
- , the initial meridian for the, a suggestion from the Bologna Academy of Science towards an agreement on, by Dr. C. Tondini de Quarenghi, 618.
- Ussher (W. A. E.), some points of interest in the geology of Somerset, 659; the Watcombe terra cotta clay, 672.

- 'v,' electrometric determination of, by Profs. Sir W. Thomson, Ayrton, and Perry, 616.
- *Valency, discussion on, 635.
- Valentine (J. S.) on the erosion of the sea-coasts of England and Wales, 898.
- *Van't Hoff's hypothesis and the constitution of benzene, J. E. Marsh on, 631.
- Vapour densities at high temperatures and under reduced pressure, the determination of, by Dr. W. Bott, 632.
- Veley (V. H.) on the rate of solution of copper in acids, 638.
- Vesuvius, on a mass containing metallic iron found on, by Dr. H. J. Johnston-Lavis, 667.
- Vesuvius and its neighbourhood, the volcanic phenomena of, report on, 320.
- Vogt (H. C.), revolving sails, or air-propellers, 820.
- Volcanic action, the causes of, J. L. Lobley on, 670.
- Volcanic phenomena of Vesuvius and its neighbourhood, report on the, 320.
- Volcanic structure, the recent, of the Azorean archipelago, O. H. Howarth on, 671.
- Volcanoes of the Two Sicilies, the, by Dr. T. Anderson, 663.
- Vortex analogue of static electricity, a, by Prof. W. M. Hicks, 577.
- Vulcano, the late eruption in the island of, Drs. T. Anderson and H. J. Johnston-Lavis on, 664.
- Wage statistics and theories, J. Mavor on, 757.
- Waist-belts and stays, the physiological bearing of, Prof. Roy and J. G. Adami on, 704.
- Walker (Gen. J. T.) on the work of the Differential Gravity Meter Committee, 72; on the desirability of further research in the Antarctic regions, 316.
- Ward (Prof. H. M.) on the steps taken for establishing a botanical station at Peradeniya, Ceylon, 421; *a lily disease, 702.
- *Wasps and bees, solitary, the instincts of, Sir J. Lubbock on, 706.
- Watcombe terra-cotta clay, W. A. E. Ussher on the, 672.
- *Water, the behaviour of, under great provocation from heat, Prof. W. Ramsay on, 562.
- Water colours, the action of light on, Dr. A. Richardson on, 641.
- *Watherston (E. J.), the industrial education of women abroad and at home, 771.
- Watts (N.), miners' electric safety-lamps, 816.
- Watts (W. W.), an igneous succession in Shropshire, 685.
- Waves in a viscous liquid, by A. B. Bassett, 563.
- Weather of 1888, the effects of the, on the animal and vegetable kingdoms, E. J. Lowe on, 726.
- Weldon (W. F. R.) on the flora of the Bahamas, 361.
- Wells (L. B.), plant and machinery in use on the Manchester ship canal, 796.
- West India Islands, report on the present state of our knowledge of the zoology and botany of the, and on the steps taken to investigate ascertained deficiencies in the fauna and flora, 437.
- Western Asia, the early races of, Major C. R. Conder on, 855.
- *Wethered (E.) on the circulation of underground waters, 145; on the lower carboniferous rocks of Gloucestershire, 657.
- Wharton (Capt. W. J. L.) on the erosion of the sea-coasts of England and Wales, 898.
- Wheat, an examination into the reasons of the price of, rising or falling contemporaneously with the variation in the value of foreign currencies, by W. J. Harris, 767.
- Whidborne (Rev. G. F.) on some Devonian cephalopods and gasteropods, 680; on some Devonian crustaceans, 681; on some fossils of the limestones of South Devon, *ib.*
- Whipple (G. M.) on the best means of comparing and reducing magnetic observations, 28.
- Whitaker (W.) on the circulation of underground waters, 145; on the work of the Corresponding Societies Committee, 255; on the extension of the Bath oolite under London as shown by a deep boring at Streatham, 656; on the erosion of the sea-coasts of England and Wales, 898.
- White (W.) on the work of the Corresponding Societies Committee, 255.
- Whitehouse (Cope), the river of Joseph, the Fayum and Raian basins, 746; the Raiyān project for the storage of Nile flood, 799.
- Williamson (Prof. A. W.) on the work of the Corresponding Societies Committee, 255.
- Williamson (Prof. W. C.) on the flora of the carboniferous rocks of Lancashire and West Yorkshire, 150.
- Wilson (Col. Sir C. W.), Address to the Geographical Section by, 729.
- Wilson (Dr. D.) on the North-western tribes of the dominion of Canada, 233.

- Wilson (Rev. E. F.), report on the Sarcee Indians, 242; notes thereon by H. Hale, 253.
- Wind values and declination disturbances at the Kew Observatory, results of a comparison between the, by Prof. Balfour Stewart and W. L. Carpenter, 28.
- *Winter (A.) on controlling the direction of rotation of a dynamo, 824.
- *Winton (Sir F. de), the commercial future of Central Africa, 745.
- Winwood (Rev. H. H.) on the Tytherington and Thornbury section, 658.
- *Women, the industrial education of, abroad and at home, by E. J. Watherston, 771.
- Wood (H. T.) on standards of light, 39.
- Woodall (J. W.) on the erosion of the sea-coasts of England and Wales, 898.
- *Woodthorpe (Col.), explorations on the Chindwin river, Upper Burmah, in 1886-87, 741.
- Woodward (A. S.), a comparison of the cretaceous fish-fauna of Mount Lebanon with that of the English chalk, 678; on *Bucklandium diluvii*, König, a siluroid fish from the London clay of Sheppey, 679.
- Woodward (Dr. H.) on the provincial museums of the United Kingdom, 124; on the 'manure' gravels of Wexford, 133; on the fossil phyllopoda of the palæozoic rocks, 173; on an ancient sea-beach near Bridlington Quay, 328.
- Woodward (H. B.), further note on the Midford sands, 650; the relations of the great oolite to the forest marble and fuller's-earth in the south-west of England, 651; note on the Portland sands of Swindon and elsewhere, 652.
- Worlebury, the ancient (præ-Roman) stronghold of, near Weston-super-Mare, some account of, by Rev. H. G. Tomkins, 851.
- Worthington (Prof. A. M.) on the stretching of liquids, 583.
- Young (Prof.) on the bibliography of solution, 54.
- Zoological station at Naples, report of the Committee appointed to arrange for the occupation of a table at the, 150; reports to the Committee: by Mr. J. Gardiner, 152; by Mr. A. D. Sloan, 153; by Prof. R. J. Anderson, 157.

BRITISH ASSOCIATION, FOR THE ADVANCEMENT OF SCIENCE.

Life Members (since 1845), and all Annual Members who have not intermitted their Subscription, receive gratis all Reports published after the date of their Membership. Any other volume they require may be obtained on application at the Office of the Association, 22 Albemarle Street, Piccadilly, London, W., at the following prices, viz.—Reports for 1831 to 1874 (*of which more than 15 copies remain*), at 2s. 6d. per volume; after that date, at two-thirds of the Publication Price. A few sets, from 1831 to 1874 inclusive, may also be obtained at £10 per set.

Associates for the Meeting in 1888 may obtain the Volume for the Year at two-thirds of the Publication Price.

PROCEEDINGS OF THE FIRST AND SECOND MEETINGS, at York and Oxford, 1831 and 1832, *Published at 13s. 6d.*

CONTENTS:—Prof. Airy, on the Progress of Astronomy;—J. W. Lubbock, on the Tides;—Prof. Forbes, on the Present State of Meteorology;—Prof. Powell, on the Present State of the Science of Radiant Heat;—Prof. Cumming, on Thermo-Electricity;—Sir D. Brewster, on the Progress of Optics;—Rev. W. Whewell, on the Present State of Mineralogy;—Rev. W. D. Conybeare, on the Recent Progress and Present State of Geology;—Dr. Pritchard's Review of Philological and Physical Researches.

Together with Papers on Mathematics, Optics, Acoustics, Magnetism, Electricity, Chemistry, Meteorology, Geography, Geology, Zoology, Anatomy, Physiology, Botany, and the Arts; and an Exposition of the Objects and Plan of the Association, &c.

PROCEEDINGS OF THE THIRD MEETING, at Cambridge, 1833, *Published at 12s. (Out of Print.)*

CONTENTS:—Proceedings of the Meeting;—John Taylor, on Mineral Veins;—Dr. Lindley, on the Philosophy of Botany;—Dr. Henry, on the Physiology of the Nervous System;—P. Barlow, on the Strength of Materials;—S. H. Christie, on the Magnetism of the Earth;—Rev. J. Challis, on the Analytical Theory of Hydrostatics and Hydrodynamics;—G. Rennie, on Hydraulics as a Branch of Engineering, Part I.;—Rev. G. Peacock, on certain Branches of Analysis.

Together with Papers on Mathematics and Physics, Philosophical Instruments and Mechanical Arts, Natural History, Anatomy, Physiology, and History of Science.

PROCEEDINGS OF THE FOURTH MEETING, at Edinburgh, 1834, *Published at 15s.*

CONTENTS:—H. G. Rogers, on the Geology of North America;—Dr. C. Henry, on the Laws of Contagion;—Prof. Clark, on Animal Physiology;—Rev. L. Jenyns, on Zoology;—Rev. J. Challis, on Capillary Attraction;—Prof. Lloyd, on Physical Optics;—G. Rennie, on Hydraulics, Part II.

Together with the Transactions of the Sections, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE FIFTH MEETING, at Dublin, 1835, *Published at 13s. 6d.* (Out of Print.)

CONTENTS :—Rev. W. Whewell, on the Recent Progress and Present Condition of the Mathematical Theories of Electricity, Magnetism, and Heat;—A. Quetelet, *Aperçu de l'Etat actuel des Sciences Mathématiques chez les Belges*;—Capt. E. Sabine, on the Phenomena of Terrestrial Magnetism.

Together with the Transactions of the Sections, Prof. Sir W. Hamilton's Address and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE SIXTH MEETING, at Bristol, 1836, *Published at 12s.* (Out of Print.)

CONTENTS :—Prof. Daubeny, on the Present State of our Knowledge with respect to Mineral and Thermal Waters;—Major E. Sabine, on the Direction and Intensity of the Terrestrial Magnetic Force in Scotland;—J. Richardson, on North American Zoology;—Rev. J. Challis, on the Mathematical Theory of Fluids;—J. T. Mackay, a Comparative View of the more remarkable Plants which characterize the neighbourhood of Dublin and Edinburgh, and the South-west of Scotland, &c.;—J. T. Mackay, Comparative Geographical Notices of the more remarkable Plants which characterize Scotland and Ireland;—Report of the London Sub-Committee of the Medical Section on the Motions and Sounds of the Heart;—Second Report of the Dublin Sub-Committee on the Motions and Sounds of the Heart;—Report of the Dublin Committee on the Pathology of the Brain and Nervous System;—J. W. Lubbock, Account of the Recent Discussions of Observations of the Tides;—Rev. B. Powell, on determining the Refractive Indices for the Standard Rays of the Solar Spectrum in various media;—Dr. Hodgkin, on the Communication between the Arteries and Absorbents;—Prof. Phillips, Report of Experiments on Subterranean Temperature;—Prof. Hamilton, on the Validity of a Method recently proposed by G. B. Jerrard, for Transforming and Resolving Equations of Elevated Degrees.

Together with the Transactions of the Sections, Prof. Daubeny's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE SEVENTH MEETING, at Liverpool, 1837, *Published at 16s. 6d.* (Out of Print.)

CONTENTS :—Major E. Sabine, on the Variations of the Magnetic Intensity observed at different points of the Earth's Surface;—Rev. W. Taylor, on the various modes of Printing for the Use of the Blind;—J. W. Lubbock, on the Discussions of Observations of the Tides;—Prof. T. Thompson, on the Difference between the Composition of Cast Iron produced by the Cold and Hot Blast;—Rev. T. R. Robinson, on the Determination of the Constant of Nutation by the Greenwich Observations;—R. W. Fox, Experiments on the Electricity of Metallic Veins, and the Temperature of Mines;—Provisional Report of the Committee of the Medical Section of the British Association, appointed to investigate the Composition of Secretions, and the Organs producing them;—Dr. G. O. Rees, Report from the Committee for inquiring into the Analysis of the Glands, &c., of the Human Body;—Second Report of the London Sub-Committee of the British Association Medical Section, on the Motions and Sounds of the Heart;—Prof. Johnston, on the Present State of our Knowledge in regard to Dimorphous Bodies;—Lieut.-Col. Sykes, on the Statistics of the four Collectories of Dukhun, under the British Government;—E. Hodgkinson, on the relative Strength and other Mechanical Properties of Iron obtained from the Hot and Cold Blast;—W. Fairbairn, on the Strength and other Properties of Iron obtained from the Hot and Cold Blast;—Sir J. Robinson and J. S. Russell, Report of the Committee on Waves;—Note by Major Sabine, being an Appendix to his Report on the Variations of the Magnetic Intensity observed at different Points of the Earth's Surface;—J. Yates, on the Growth of Plants under Glass, and without any free communication with the outward Air, on the Plan of Mr. N. J. Ward, of London.

Together with the Transactions of the Sections, Prof. Traill's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE EIGHTH MEETING, at Newcastle, 1838,
Published at 15s. (Out of Print.)

CONTENTS:—Rev. W. Whewell, Account of a Level Line, measured from the Bristol Channel to the English Channel, by Mr. Bunt;—Report on the Discussions of Tides, prepared under the direction of the Rev. W. Whewell;—W. S. Harris, Account of the Progress and State of the Meteorological Observations at Plymouth;—Major E. Sabine, on the Magnetic Isoclinal and Isodynamic Lines in the British Islands;—Dr. Lardner, on the Determination of the Mean Numerical Values of Railway Constants;—R. Mallet, First Report upon Experiments upon the Action of Sea and River Water upon Cast and Wrought Iron;—R. Mallet, on the Action of a Heat of 212° Fahr., when long continued, on Inorganic and Organic Substances.

Together with the Transactions of the Sections, Mr. Murchison's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE NINTH MEETING, at Birmingham, 1839,
Published at 13s. 6d. (Out of Print.)

CONTENTS:—Rev. B. Powell, Report on the Present State of our Knowledge of Refractive Indices, for the Standard Rays of the Solar Spectrum in different media; Report on the Application of the Sum assigned for Tide Calculations to Rev. W. Whewell, in a letter from T. G. Bunt, Esq.;—H. L. Pattinson, on some Galvanic Experiments to determine the Existence or Non-Existence of Electrical Currents among Stratified Rocks, particularly those of the Mountain Limestone formation, constituting the Lead Measures of Alton Moor;—Sir D. Brewster, Reports respecting the Two Series of Hourly Meteorological Observations kept in Scotland;—Report on the subject of a series of Resolutions adopted by the British Association at their Meeting in August 1838, at Newcastle;—R. Owen, Report on British Fossil Reptiles;—E. Forbes, Report on the Distribution of the Pulmoniferous Mollusca in the British Isles;—W. S. Harris, Third Report on the Progress of the Hourly Meteorological Register at Plymouth Dockyard.

Together with the Transactions of the Sections, Rev. W. Vernon Harcourt's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE TENTH MEETING, at Glasgow, 1840,
Published at 15s. (Out of Print.)

CONTENTS:—Rev. B. Powell, Report on the Recent Progress of discovery relative to Radiant Heat, supplementary to a former Report on the same subject inserted in the first volume of the Reports of the British Association for the Advancement of Science;—J. D. Forbes, Supplementary Report on Meteorology;—W. S. Harris, Report on Prof. Whewell's Anemometer, now in operation at Plymouth;—Report on 'The Motion and Sounds of the Heart,' by the London Committee of the British Association, for 1839-40;—Prof. Schönbein, an Account of Researches in Electro-Chemistry;—B. Mallet, Second Report upon the Action of Air and Water, whether fresh or salt, clear or foul, and at various temperatures, upon Cast Iron, Wrought Iron, and Steel;—R. W. Fox, Report on some Observations on Subterranean Temperature;—A. F. Osler, Report on the Observations recorded during the years 1837, 1838, 1839, and 1840, by the Self-registering Anemometer erected at the Philosophical Institution, Birmingham;—Sir D. Brewster, Report respecting the Two Series of Hourly Meteorological Observations kept at Inverness and Kingussie, from Nov. 1st, 1838, to Nov. 1st, 1839;—W. Thompson, Report on the Fauna of Ireland: Div. *Vertebrata*;—C. J. B. Williams, M.D., Report of Experiments on the Physiology of the Lungs and Air-Tubes;—Rev. J. S. Henslow, Report of the Committee on the Preservation of Animal and Vegetable Substances.

Together with the Transactions of the Sections, Mr. Murchison and Major E. Sabine's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE ELEVENTH MEETING, at Plymouth, 1841, Published at 13s. 6d.

CONTENTS:—Rev. P. Kelland, on the Present State of our Theoretical and Experimental Knowledge of the Laws of Conduction of Heat;—G. L. Roupell, M.D.,

Report on Poisons;—T. G. Bunt, Report on Discussions of Bristol Tides, under the direction of the Rev. W. Whewell;—D. Ross, Report on the Discussions of Leith Tide Observations, under the direction of the Rev. W. Whewell;—W. S. Harris, upon the working of Whewell's Anemometer at Plymouth during the past year;—Report of a Committee appointed for the purpose of superintending the scientific co-operation of the British Association in the System of Simultaneous Observations in Terrestrial Magnetism and Meteorology;—Reports of Committees appointed to provide Meteorological Instruments for the use of M. Agassiz and Mr. M'Cord;—Report of a Committee appointed to superintend the Reduction of Meteorological Observations;—Report of a Committee for revising the Nomenclature of the Stars;—Report of a Committee for obtaining Instruments and Registers to record Shocks and Earthquakes in Scotland and Ireland;—Report of a Committee on the Preservation of Vegetative Powers in Seeds;—Dr. Hodgkin, on Inquiries into the Races of Man;—Report of the Committee appointed to report how far the Desiderata in our knowledge of the Condition of the Upper Strata of the Atmosphere may be supplied by means of Ascents in Balloons or otherwise, to ascertain the probable expense of such Experiments, and to draw up Directions for Observers in such circumstances;—R. Owen, Report on British Fossil Reptiles;—Reports on the Determination of the Mean Value of Railway Constants;—Dr. D. Lardner, Second and concluding Report on the Determination of the Mean Value of Railway Constants;—E. Woods, Report on Railway Constants;—Report of a Committee on the Construction of a Constant Indicator for Steam Engines.

Together with the Transactions of the Sections, Prof. Whewell's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE TWELFTH MEETING, at Manchester, 1842, *Published at 10s. 6d.*

CONTENTS:—Report of the Committee appointed to conduct the co-operation of the British Association in the System of Simultaneous Magnetical and Meteorological Observations;—Dr. J. Richardson, Report on the present State of the Ichthyology of New Zealand;—W. S. Harris, Report on the Progress of Meteorological Observations at Plymouth;—Second Report of a Committee appointed to make Experiments on the Growth and Vitality of Seeds;—C. Vignoles, Report of the Committee on Railway Sections;—Report of the Committee for the Preservation of Animal and Vegetable Substances;—Dr. Lyon Playfair, Abstract of Prof. Liebig's Report on Organic Chemistry applied to Physiology and Pathology;—R. Owen, Report on the British Fossil Mammalia, Part I.;—R. Hunt, Researches on the Influence of Light on the Germination of Seeds and the Growth of Plants;—L. Agassiz, Report on the Fossil Fishes of the Devonian System or Old Red Sandstone;—W. Fairbairn, Appendix to a Report on the Strength and other Properties of Cast Iron obtained from the Hot and Cold Blast;—D. Milne, Report of the Committee for Registering Shocks of Earthquakes in Great Britain;—Report of a Committee on the construction of a Constant Indicator for Steam-Engines, and for the determination of the Velocity of the Piston of the Self-acting Engine at different periods of the Stroke;—J. S. Russell, Report of a Committee on the Form of Ships;—Report of a Committee appointed 'to consider of the Rules by which the Nomenclature of Zoology may be established on a uniform and permanent basis;—Report of a Committee on the Vital Statistics of Large Towns in Scotland;—Provisional Reports, and Notices of Progress in Special Researches entrusted to Committees and Individuals.

Together with the Transactions of the Sections, Lord Francis Egerton's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE THIRTEENTH MEETING, at Cork, 1843, *Published at 12s.*

CONTENTS:—Robert Mallet, Third Report upon the Action of Air and Water, whether fresh or salt, clear or foul, and at Various Temperatures, upon Cast Iron, Wrought Iron, and Steel;—Report of the Committee appointed to conduct the Co-operation of the British Association in the System of Simultaneous Magnetical and Meteorological Observations;—Sir J. F. W. Herschel, Bart., Report of the Committee appointed for the Reduction of Meteorological Observations;—Report of the Committee appointed for Experiments on Steam-Engines;—Report of the Committee ap-

pointed to continue their Experiments on the Vitality of Seeds;—J. S. Russell, Report of a Series of Observations on the Tides of the Frith of Forth and the East Coast of Scotland;—J. S. Russell, Notice of a Report of the Committee on the Form of Ships;—J. Blake, Report on the Physiological Action of Medicines;—Report of the Committee on Zoological Nomenclature;—Report of the Committee for Registering the Shocks of Earthquakes, and making such Meteorological Observations as may appear to them desirable;—Report of the Committee for conducting Experiments with Captive Balloons;—Prof. Wheatstone, Appendix to the Report;—Report of the Committee for the Translation and Publication of Foreign Scientific Memoirs;—C. W. Peach, on the Habits of the Marine Testacea;—E. Forbes, Report on the Mollusca and Radiata of the Ægean Sea, and on their distribution, considered as bearing on Geology;—L. Agassiz, Synoptical Table of British Fossil Fishes, arranged in the order of the Geological Formations;—R. Owen, Report on the British Fossil Mammalia, Part II.;—E. W. Binney, Report on the excavation made at the junction of the Lower New Red Sandstone with the Coal Measures at Collyhurst;—W. Thompson, Report on the Fauna of Ireland: Div. *Invertebrata*;—Provisional Reports, and Notices of Progress in Special Researches entrusted to Committees and Individuals.

Together with the Transactions of the Sections, the Earl of Rosse's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE FOURTEENTH MEETING, at York, 1844, *Published at £1.*

CONTENTS:—W. B. Carpenter, on the Microscopic Structure of Shells;—J. Alder and A. Hancock, Report on the British Nudibranchiate Mollusca;—R. Hunt, Researches on the Influence of Light on the Germination of Seeds and the Growth of Plants;—Report of a Committee appointed by the British Association in 1840, for revising the Nomenclature of the Stars;—Lieut.-Col. Sabine, on the Meteorology of Toronto in Canada;—J. Blackwall, Report on some recent researches into the Structure, Functions, and Economy of the *Araneidea* made in Great Britain;—Earl of Rosse, on the Construction of large Reflecting Telescopes;—Rev. W. V. Harcourt, Report on a Gas-furnace for Experiments on Vitrification and other Applications of High Heat in the Laboratory;—Report of the Committee for Registering Earthquake Shocks in Scotland;—Report of a Committee for Experiments on Steam-Engines;—Report of the Committee to investigate the Varieties of the Human Race;—Fourth Report of a Committee appointed to continue their Experiments on the Vitality of Seeds;—W. Fairbairn, on the Consumption of Fuel and the Prevention of Smoke;—F. Ronalds, Report concerning the Observatory of the British Association at Kew;—Sixth Report of the Committee appointed to conduct the Co-operation of the British Association in the System of Simultaneous Magnetical and Meteorological Observations;—Prof. Forchhammer on the influence of Fucoidal Plants upon the Formations of the Earth, on Metamorphism in general, and particularly the Metamorphosis of the Scandinavian Alum Slate;—H. E. Strickland, Report on the Recent Progress and Present State of Ornithology;—T. Oldham, Report of Committee appointed to conduct Observations on Subterranean Temperature in Ireland;—Prof. Owen, Report on the Extinct Mammals of Australia, and descriptions of certain Fossils indicative of the former existence in that continent of large Marsupial Representatives of the Order Pachydermata;—W. S. Harris, Report on the working of Whewell and Osler's Anemometers at Plymouth, for the years 1841, 1842, 1843;—W. R. Birt, Report on Atmospheric Waves;—L. Agassiz, Rapport sur les Poissons Fossiles de l'Argile de Londres, with translation;—J. S. Russell, Report on Waves;—Provisional Reports, and Notices of Progress in Special Researches entrusted to Committees and Individuals.

Together with the Transactions of the Sections, the Dean of Ely's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE FIFTEENTH MEETING, at Cambridge, 1845, *Published at 12s.*

CONTENTS:—Seventh Report of a Committee appointed to conduct the Co-operation of the British Association in the System of Simultaneous Magnetical and Meteorological Observations;—Lieut.-Col. Sabine, on some Points in the Meteorology

of Bombay ;—J. Blake, Report on the Physiological Actions of Medicines ;—Dr. Von Boguslawski, on the Comet of 1843 ;—R. Hunt, Report on the Actinograph ;—Prof. Schönbein, on Ozone ;—Prof. Erman, on the Influence of Friction upon Thermo-Electricity ;—Baron Senftenberg, on the Self-registering Meteorological Instruments employed in the Observatory at Senftenberg ;—W. R. Birt, Second Report on Atmospheric Waves ;—G. R. Porter, on the Progress and Present Extent of Savings Banks in the United Kingdom ;—Prof. Bunsen and Dr. Playfair, Report on the Gases evolved from Iron Furnaces, with reference to the Theory of Smelting of Iron ;—Dr. Richardson, Report on the Ichthyology of the Seas of China and Japan ;—Report of the Committee on the Registration of Periodical Phenomena of Animals and Vegetables ;—Fifth Report of the Committee on the Vitality of Seeds ;—Appendix, &c.

Together with the Transactions of the Sections, Sir J. F. W. Herschel's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE SIXTEENTH MEETING, at Southampton, 1846, *Published at 15s.*

CONTENTS :—G. G. Stokes, Report on Recent Researches in Hydrodynamics ;—Sixth Report of the Committee on the Vitality of Seeds ;—Dr. Schunck, on the Colouring Matters of Madder ;—J. Blake, on the Physiological Action of Medicines ;—R. Hunt, Report on the Actinograph ;—R. Hunt, Notices on the Influence of Light on the Growth of Plants ;—R. L. Ellis, on the Recent Progress of Analysis ;—Prof. Forchhammer, on Comparative Analytical Researches on Sea Water ;—A. Erman, on the Calculation of the Gaussian Constants for 1829 ;—G. R. Porter, on the Progress, present Amount, and probable future Condition of the Iron Manufacture in Great Britain ;—W. R. Birt, Third Report on Atmospheric Waves ;—Prof. Owen, Report on the Archetype and Homologies of the Vertebrate Skeleton ;—J. Phillips, on Anemometry ;—Dr. J. Percy, Report on the Crystalline Flags ;—Addenda to Mr. Birt's Report on Atmospheric Waves.

Together with the Transactions of the Sections, Sir R. I. Murchison's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE SEVENTEENTH MEETING, at Oxford, 1847, *Published at 18s.*

CONTENTS :—Prof. Langberg, on the Specific Gravity of Sulphuric Acid at different degrees of dilution, and on the relation which exists between the Development of Heat and the coincident contraction of Volume in Sulphuric Acid when mixed with Water ;—R. Hunt, Researches on the Influence of the Solar Rays on the Growth of Plants ;—R. Mallet, on the Facts of Earthquake Phenomena ;—Prof. Nilsson, on the Primitive Inhabitants of Scandinavia ;—W. Hopkins, Report on the Geological Theories of Elevation and Earthquakes ;—Dr. W. B. Carpenter, Report on the Microscopic Structure of Shells ;—Rev. W. Whewell and Sir James C. Ross, Report upon the Recommendation of an Expedition for the purpose of completing our Knowledge of the Tides ;—Dr. Schunck, on Colouring Matters ;—Seventh Report of the Committee on the Vitality of Seeds ;—J. Glynn, on the Turbine or Horizontal Water-Wheel of France and Germany ;—Dr. R. G. Latham, on the present state and recent progress of Ethnographical Philology ;—Dr. J. C. Prichard, on the various methods of Research which contribute to the Advancement of Ethnology, and of the relations of that Science to other branches of Knowledge ;—Dr. C. C. J. Bunsen, on the results of the recent Egyptian researches in reference to Asiatic and African Ethnology, and the Classification of Languages ;—Dr. C. Meyer, on the Importance of the Study of the Celtic Language as exhibited by the Modern Celtic Dialects still extant ;—Dr. Max Müller, on the Relation of the Bengali to the Aryan and Aboriginal Languages of India ;—W. R. Birt, Fourth Report on Atmospheric Waves ;—Prof. W. H. Dove, Temperature Tables, with Introductory Remarks by Lieut.-Col. E. Sabine ;—A. Erman and H. Petersen, Third Report on the Calculation of the Gaussian Constants for 1829.

Together with the Transactions of the Sections, Sir Robert Harry Inglis's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE EIGHTEENTH MEETING, at Swansea, 1848, *Published at 9s.*

CONTENTS:—Rev. Prof. Powell, A Catalogue of Observations of Luminous Meteors;—J. Glynn, on Water-pressure Engines;—R. A. Smith, on the Air and Water of Towns;—Eighth Report of Committee on the Growth and Vitality of Seeds;—W. R. Birt, Fifth Report on Atmospheric Waves;—E. Schunck, on Colouring Matters;—J. P. Budd, on the advantageous use made of the gaseous escape from the Blast Furnaces at the Ystalyfera Iron Works;—R. Hunt, Report of progress in the investigation of the Action of Carboric Acid on the Growth of Plants allied to those of the Coal Formations;—Prof. H. W. Dove, Supplement to the Temperature Tables printed in the Report of the British Association for 1847;—Remarks by Prof. Dove on his recently constructed Maps of the Monthly Isothermal Lines of the Globe, and on some of the principal Conclusions in regard to Climatology deducible from them; with an introductory Notice by Lieut.-Col. E. Sabine;—Dr. Daubeny, on the progress of the investigation on the Influence of Carbonic Acid on the Growth of Ferns;—J. Phillips, Notice of further progress in Anemometrical Researches;—Mr. Mallet's Letter to the Assistant-General Secretary;—A. Erman, Second Report on the Gaussian Constants;—Report of a Committee relative to the expediency of recommending the continuance of the Toronto Magnetical and Meteorological Observatory until December 1850.

Together with the Transactions of the Sections, the Marquis of Northampton's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE NINETEENTH MEETING, at Birmingham, 1849, *Published at 10s.*

CONTENTS:—Rev. Prof. Powell, A Catalogue of Observations of Luminous Meteors;—Earl of Rosse, Notice of Nebulæ lately observed in the Six-foot Reflector;—Prof. Daubeny, on the Influence of Carbonic Acid Gas on the health of Plants, especially of those allied to the Fossil Remains found in the Coal Formation;—Dr. Andrews, Report on the Heat of Combination;—Report of the Committee on the Registration of the Periodic Phenomena of Plants and Animals;—Ninth Report of Committee on Experiments on the Growth and Vitality of Seeds;—F. Ronalds, Report concerning the Observatory of the British Association at Kew, from Aug. 9, 1848 to Sept. 12, 1849;—R. Mallet, Report on the Experimental Inquiry on Railway Bar Corrosion;—W. R. Birt, Report on the Discussion of the Electrical Observations at Kew.

Together with the Transactions of the Sections, the Rev. T. R. Robinson's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE TWENTIETH MEETING, at Edinburgh, 1850, *Published at 15s.* (Out of Print.)

CONTENTS:—R. Mallet, First Report on the Facts of Earthquake Phenomena;—Rev. Prof. Powell, on Observations of Luminous Meteors;—Dr. T. Williams, on the Structure and History of the British Annelida;—T. C. Hunt, Results of Meteorological Observations taken at St. Michael's from the 1st of January, 1840, to the 31st of December, 1849;—R. Hunt, on the present State of our Knowledge of the Chemical Action of the Solar Radiations;—Tenth Report of Committee on Experiments on the Growth and Vitality of Seeds;—Major-Gen. Briggs, Report on the Aboriginal Tribes of India;—F. Ronalds, Report concerning the Observatory of the British Association at Kew;—E. Forbes, Report on the Investigation of British Marine Zoology by means of the Dredge;—R. MacAndrew, Notes on the Distribution and Range in depth of Mollusca and other Marine Animals, observed on the coasts of Spain, Portugal, Barbary, Malta, and Southern Italy in 1849;—Prof. Allman, on the Present State of our Knowledge of the Freshwater Polyzoa;—Registration of the Periodical Phenomena of Plants and Animals;—Suggestions to Astronomers for the Observation of the Total Eclipse of the Sun on July 28, 1851.

Together with the Transactions of the Sections, Sir David Brewster's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE TWENTY-FIRST MEETING, at Ipswich, 1851, Published at 16s. 6d.

CONTENTS:—Rev. Prof. Powell, on Observations of Luminous Meteors;—Eleventh Report of Committee on Experiments on the Growth and Vitality of Seeds;—Dr. J. Drew, on the Climate of Southampton;—Dr. R. A. Smith, on the Air and Water of Towns: Action of Porous Strata, Water, and Organic Matter;—Report of the Committee appointed to consider the probable Effects in an Economical and Physical Point of View of the Destruction of Tropical Forests;—A. Henfrey, on the Reproduction and supposed Existence of Sexual Organs in the Higher Cryptogamous Plants;—Dr. Daubeny, on the Nomenclature of Organic Compounds;—Rev. Dr. Donaldson, on two unsolved Problems in Indo-German Philology;—Dr. T. Williams, Report on the British Annelida;—R. Mallet, Second Report on the Facts of Earthquake Phenomena;—Letter from Prof. Henry to Col. Sabine, on the System of Meteorological Observations proposed to be established in the United States;—Col. Sabine, Report on the Kew Magnetographs;—J. Welsh, Report on the Performance of his three Magnetographs during the Experimental Trial at the Kew Observatory;—F. Ronalds, Report concerning the Observatory of the British Association at Kew, from September 12, 1850, to July 31, 1851;—Ordnance Survey of Scotland.

Together with the Transactions of the Sections, Prof. Airy's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE TWENTY-SECOND MEETING, at Belfast, 1852, Published at 15s.

CONTENTS:—R. Mallet, Third Report on the Facts of Earthquake Phenomena;—Twelfth Report of Committee on Experiments on the Growth and Vitality of Seeds;—Rev. Prof. Powell, Report on Observations of Luminous Meteors, 1851–52;—Dr. Gladstone, on the Influence of the Solar Radiations on the Vital Powers of Plants;—A Manual of Ethnological Inquiry;—Col. Sykes, Mean Temperature of the Day, and Monthly Fall of Rain at 127 Stations under the Bengal Presidency;—Prof. J. D. Forbes, on Experiments on the Laws of the Conduction of Heat;—R. Hunt, on the Chemical Action of the Solar Radiations;—Dr. Hodges, on the Composition and Economy of the Flax Plant;—W. Thompson, on the Freshwater Fishes of Ulster;—W. Thompson, Supplementary Report on the Fauna of Ireland;—W. Wills, on the Meteorology of Birmingham;—J. Thomson, on the Vortex-Water-Wheel;—J. B. Lawes and Dr. Gilbert, on the Composition of Foods in relation to Respiration and the Feeding of Animals.

Together with the Transactions of the Sections, Colonel Sabine's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE TWENTY-THIRD MEETING, at Hull, 1853, Published at 10s. 6d.

CONTENTS:—Rev. Prof. Powell, Report on Observations of Luminous Meteors, 1852–53;—James Oldham, on the Physical Features of the Humber;—James Oldham, on the Rise, Progress, and Present Position of Steam Navigation in Hull;—William Fairbairn, Experimental Researches to determine the Strength of Locomotive Boilers, and the causes which lead to Explosion;—J. J. Sylvester, Provisional Report on the Theory of Determinants;—Professor Hodges, M.D., Report on the Gases evolved in Steeping Flax, and on the Composition and Economy of the Flax Plant;—Thirteenth Report of Committee on Experiments on the Growth and Vitality of Seeds;—Robert Hunt, on the Chemical Action of the Solar Radiations;—Dr. John P. Bell, Observations on the Character and Measurements of Degradation of the Yorkshire Coast;—First Report of Comitée on the Physical Character of the Moon's Surface, as compared with that of the Earth;—R. Mallet, Provisional Report on Earthquake Wave-Transits; and on Seismometrical Instruments;—William Fairbairn, on the Mechanical Properties of Metals as derived from repeated Meltings, exhibiting the maximum point of strength and the causes of deterioration;—Robert Mallet, Third Report on the Facts of Earthquake Phenomena (continued).

Together with the Transactions of the Sections, Mr. Hopkins's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE TWENTY-FOURTH MEETING, at Liverpool, 1854, *Published at 18s.*

CONTENTS:—R. Mallet, Third Report on the Facts of Earthquake Phenomena (continued);—Major-General Chesney, on the Construction and General Use of Efficient Life-Boats;—Rev. Prof. Powell, Third Report on the present State of our Knowledge of Radiant Heat;—Colonel Sabine, on some of the results obtained at the "British Colonial Magnetic Observatories";—Colonel Portlock, Report of the Committee on Earthquakes, with their proceedings respecting Seismometers;—Dr. Gladstone, on the Influence of the Solar Radiations on the Vital Powers of Plants, Part 2;—Rev. Prof. Powell, Report on Observations of Luminous Meteors, 1853-54;—Second Report of the Committee on the Physical Character of the Moon's Surface;—W. G. Armstrong, on the Application of Water-Pressure Machinery;—J. B. Lawes and Dr. Gilbert, on the Equivalency of Starch and Sugar in Food;—Archibald Smith, on the Deviations of the Compass in Wooden and Iron Ships;—Fourteenth Report of Committee on Experiments on the Growth and Vitality of Seeds.

Together with the Transactions of the Sections, the Earl of Harrowby's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE TWENTY-FIFTH MEETING, at Glasgow, 1855, *Published at 15s.*

CONTENTS:—T. Dobson, Report on the Relation between Explosions in Coal-Mines and Revolving Storms;—Dr. Gladstone, on the Influence of the Solar Radiations on the Vital Powers of Plants growing under different Atmospheric Conditions, Part 3;—C. Spence Bate, on the British Edriophthalma;—J. F. Bateman, on the present state of our knowledge on the Supply of Water to Towns;—Fifteenth Report of Committee on Experiments on the Growth and Vitality of Seeds;—Rev. Prof. Powell, Report on Observations of Luminous Meteors, 1854-55;—Report of Committee appointed to inquire into the best means of ascertaining those properties of Metals and effects of various modes of treating them which are of importance to the durability and efficiency of Artillery;—Rev. Prof. Henslow, Report on Typical Objects in Natural History;—A. Follett Osler, Account of the Self-registering Anemometer and Rain-Gauge at the Liverpool Observatory;—Provisional Reports.

Together with the Transactions of the Sections, the Duke of Argyll's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE TWENTY-SIXTH MEETING, at Cheltenham, 1856, *Published at 18s.*

CONTENTS:—Report from the Committee appointed to investigate and report upon the effects produced upon the Channels of the Mersey by the alterations which within the last fifty years have been made in its Banks;—J. Thomson, Interim Report on progress in Researches on the Measurement of Water by Weir Boards;—Dredging Report, Frith of Clyde, 1856;—Rev. B. Powell, Report on Observations of Luminous Meteors, 1855-1856;—Prof. Bunsen and Dr. H. E. Roscoe, Photochemical Researches;—Rev. James Booth, on the Trigonometry of the Parabola, and the Geometrical Origin of Logarithms;—R. MacAndrew, Report on the Marine Testaceous Mollusca of the North-east Atlantic and neighbouring Seas, and the physical conditions affecting their development;—P. P. Carpenter, Report on the present state of our knowledge with regard to the Mollusca of the West Coast of North America;—T. C. Eyton, Abstract of First Report on the Oyster Beds and Oysters of the British Shores;—Prof. Phillips, Report on Cleavage, and Foliation in Rocks, and on the Theoretical Explanations of these Phenomena, Part 1;—Dr. T. Wright, on the Stratigraphical Distribution of the Oolitic Echinodermata;—W. Fairbairn, on the Tensile Strength of Wrought Iron at various Temperatures;—C. Atherton, on Mercantile Steam Transport Economy;—J. S. Bowerbank, on the Vital Powers of the Spongiadæ;—Report of a Committee upon the Experiments conducted at Stormontfield, near Perth, for the artificial propagation of Salmon;—Provisional Report on the Measurement of Ships for Tonnage;—On Typical Forms of Minerals, Plants and Animals for Museums;—J. Thomson, Interim Report on Progress in Researches on the Measurement of Water by Weir Boards;—R. Mallet, on

Observations with the Seismometer;—A. Cayley, on the Progress of Theoretical Dynamics;—Report of a Committee appointed to consider the formation of a Catalogue of Philosophical Memoirs.

Together with the Transactions of the Sections, Dr. Daubeny's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE TWENTY-SEVENTH MEETING, at Dublin, 1857, *Published at 15s.*

CONTENTS:—A. Cayley, Report on the recent progress of Theoretical Dynamics;—Sixteenth and Final Report of Committee on Experiments on the Growth and Vitality of Seeds;—James Oldham, C.E., continuation of Report on Steam Navigation at Hull;—Report of a Committee on the Defects of the present methods of Measuring and Registering the Tonnage of Shipping, as also of Marine Engine-Power, and to frame more perfect rules, in order that a correct and uniform principle may be adopted to estimate the Actual Carrying Capabilities and Working-power of Steam Ships;—Robert Were Fox, Report on the Temperature of some Deep Mines in Cornwall;—Dr. G. Plarr, de quelques Transformations de la Somme $\sum_{t=0}^{t=a} \frac{a^t + {}^1\beta^t + {}^1\delta^t + {}^1\epsilon^t + {}^1\gamma^t}{1 + {}^1\gamma^t + {}^1\epsilon^t + {}^1\delta^t + {}^1\beta^t + {}^1\alpha^t}$ a étant entier négatif, et de quelques cas dans lesquels cette somme est exprimable par une combinaison de factorielles, la notation $a^t + {}^1$ désignant le produit des facteurs $a (a+1) (a+2) \&c. \dots (a+t-1)$;—G. Dickie, M.D., Report on the Marine Zoology of Strangford Lough, County Down, and corresponding part of the Irish Channel;—Charles Atherton, Suggestions for Statistical Inquiry into the Extent to which Mercantile Steam Transport Economy is affected by the Constructive Type of Shipping, as respects the Proportions of Length, Breadth, and Depth;—J. S. Bowerbank, Further Report on the Vitality of the Spongiadæ;—Dr. John P. Hodges, on Flax;—Major-General Sabine, Report of the Committee on the Magnetic Survey of Great Britain;—Rev. Baden Powell, Report on Observations of Luminous Meteors, 1856–57;—C. Vignoles, on the Adaptation of Suspension Bridges to sustain the passage of Railway Trains;—Prof. W. A. Miller, on Electro-Chemistry;—John Simpson, Results of Thermometrical Observations made at the *Plover's* Wintering-place, Point Barrow, latitude $71^\circ 21' N.$, long. $156^\circ 17' W.$, in 1852–54;—Charles James Hargreave, on the Algebraic Couple; and on the Equivalents of Indeterminate Expressions;—Thomas Grubb, Report on the Improvement of Telescope and Equatorial Mountings;—Prof. James Buckman, Report on the Experimental Plots in the Botanical Garden of the Royal Agricultural College at Cirencester;—William Fairbairn, on the Resistance of Tubes to Collapse;—George C. Hyndman, Report of the Proceedings of the Belfast Dredging Committee;—Peter W. Barlow, on the Mechanical Effect of combining Girders and Suspension Chains, and a Comparison of the Weight of Metal in Ordinary and Suspension Girders, to produce equal deflections with a given load;—J. Park Harrison, Evidences of Lunar Influence on Temperature;—Report on the Animal and Vegetable Products imported into Liverpool from the years 1851 to 1855 (inclusive);—Andrew Henderson, Report on the Statistics of Life-boats and Fishing-boats on the Coasts of the United Kingdom.

Together with the Transactions of the Sections, the Rev. H. Lloyd's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE TWENTY-EIGHTH MEETING, at Leeds, September 1858, *Published at 20s.*

CONTENTS:—R. Mallet, Fourth Report upon the Facts and Theory of Earthquake Phenomena;—Rev. Prof. Powell, Report on Observations of Luminous Meteors, 1857–1858;—R. H. Meade, on some Points in the Anatomy of the Araneidea or true Spiders, especially on the internal structure of their Spinning Organs;—W. Fairbairn, Report of the Committee on the Patent Laws;—S. Eddy, on the Lead Mining Districts of Yorkshire;—W. Fairbairn, on the Collapse of Glass Globes and Cylinders;—Dr. E. Perceval Wright and Prof. J. Reay Greene, Report on the Marine Fauna of the South and West Coasts of Ireland;—Prof. J. Thomson, on Experiments on the Measurement of Water by Triangular Notches in Weir Boards;—Major-General Sabine, Report of the Committee on the Magnetic Survey of Great Britain;—Michael Connel and William Keddie, Report on Animal, Vegetable, and Mineral Substances imported from Foreign Countries into the Clyde (including the Ports of Glasgow, Greenock,

and Port Glasgow) in the years 1853, 1854, 1855, 1856, and 1857;—Report of the Committee on Shipping Statistics;—Rev. H. Lloyd, D.D., Notice of the Instruments employed in the Magnetic Survey of Ireland, with some of the Results;—Prof. J. R. Kinahan, Report of Dublin Dredging Committee, appointed 1857–58;—Prof. J. R. Kinahan, Report on Crustacea of Dublin District;—Andrew Henderson, on River Steamers, their Form, Construction, and Fittings, with reference to the necessity for improving the present means of Shallow-Water Navigation on the Rivers of British India;—George C. Hyndman, Report of the Belfast Dredging Committee;—Appendix to Mr. Vignoles' Paper 'On the Adaptation of Suspension Bridges to sustain the passage of Railway Trains;—Report of the Joint Committee of the Royal Society and the British Association, for procuring a continuance of the Magnetic and Meteorological Observatories;—R. Beckley, Description of a Self-recording Anemometer.

Together with the Transactions of the Sections, Prof. Owen's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE TWENTY-NINTH MEETING, at Aberdeen, September 1859, *Published at 15s.*

CONTENTS:—George C. Foster, Preliminary Report on the Recent Progress and Present State of Organic Chemistry;—Professor Buckman, Report on the Growth of Plants in the Garden of the Royal Agricultural College, Cirencester;—Dr. A. Voelcker, Report on Field Experiments and Laboratory Researches on the Constituents of Manures essential to Cultivated Crops;—A. Thomson, of Banchory, Report on the Aberdeen Industrial Feeding Schools;—On the Upper Silurians of Lesmahagow, Lanarkshire;—Alphonse Gages, Report on the Results obtained by the Mechanico-Chemical Examination of Rocks and Minerals;—William Fairbairn, Experiments to determine the Efficiency of Continuous and Self-acting Brakes for Railway Trains;—Professor J. R. Kinahan, Report of Dublin Bay Dredging Committee for 1858–59;—Rev. Baden Powell, Report on Observations of Luminous Meteors for 1858–59;—Professor Owen, Report on a Series of Skulls of various Tribes of Mankind inhabiting Nepal, collected, and presented to the British Museum, by Bryan H. Hodgson, Esq., late Resident in Nepal, &c. &c.;—Messrs. Maskelyne, Hadow, Hardwich, and Llewelyn, Report on the Present State of our Knowledge regarding the Photographic Image;—G. C. Hyndman, Report of the Belfast Dredging Committee for 1859;—James Oldham, Continuation of Report of the Progress of Steam Navigation at Hull;—Charles Atherton, Mercantile Steam Transport Economy as affected by the Consumption of Coals;—Warren De La Rue, Report on the present state of Celestial Photography in England;—Professor Owen, on the Orders of Fossil and Recent Reptilia, and their Distribution in Time;—Balfour Stewart, on some Results of the Magnetic Survey of Scotland in the years 1857 and 1858, undertaken, at the request of the British Association, by the late John Welsh, Esq., F.R.S.;—W. Fairbairn, The Patent Laws: Report of Committee on the Patent Laws;—J. Park Harrison, Lunar Influence on the Temperature of the Air;—Balfour Stewart, an Account of the Construction of the Self-recording Magnetographs at present in operation at the Kew Observatory of the British Association;—Professor H. J. Stephen Smith, Report on the Theory of Numbers, Part I.;—Report of the Committee on Steamship Performance;—Report of the Proceedings of the Balloon Committee of the British Association appointed at the Meeting at Leeds;—Prof. William K. Sullivan, Preliminary Report on the Solubility of Salts at Temperatures above 100° Cent., and on the Mutual Action of Salts in Solution.

Together with the Transactions of the Sections, Prince Albert's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE THIRTIETH MEETING, at Oxford, June and July 1860, *Published at 15s.*

CONTENTS:—James Glaisher, Report on Observations of Luminous Meteors, 1859–60;—J. R. Kinahan, Report of Dublin Bay Dredging Committee;—Rev. J. Anderson, Report on the Excavations in Dura Den;—Prof. Buckman, Report on the Experimental Plots in the Botanical Garden of the Royal Agricultural College, Cirencester;—Rev. R. Walker, Report of the Committee on Balloon Ascents;—Prof. W. Thomson, Report of Committee appointed to prepare a Self-recording Atmo-

spheric Electrometer for Kew, and Portable Apparatus for observing Atmospheric Electricity;—William Fairbairn, Experiments to determine the Effect of Vibratory Action and long-continued Changes of Load upon Wrought-iron Girders;—R. P. Greg, Catalogue of Meteorites and Fireballs, from A.D. 2 to A.D. 1860;—Prof. H. J. S. Smith, Report on the Theory of Numbers, Part II.;—Vice-Admiral Moorsom, on the Performance of Steam-vessels, the Functions of the Screw, and the Relations of its Diameter and Pitch to the Form of the Vessel;—Rev. W. V. Harcourt, Report on the Effects of long-continued Heat, illustrative of Geological Phenomena;—Second Report of the Committee on Steamship Performance;—Interim Report on the Gauging of Water by Triangular Notches;—List of the British Marine Invertebrate Fauna.

Together with the Transactions of the Sections, Lord Wrottesley's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE THIRTY-FIRST MEETING, at Manchester, September 1861, *Published at £1.*

CONTENTS:—James Glaisher, Report on Observations of Luminous Meteors;—Dr. E. Smith, Report on the Action of Prison Diet and Discipline on the Bodily Functions of Prisoners, Part I.;—Charles Atherton, on Freight as affected by Differences in the Dynamic Properties of Steamships;—Warren De La Rue, Report on the Progress of Celestial Photography since the Aberdeen Meeting;—B. Stewart, on the Theory of Exchanges, and its recent extension;—Drs. E. Schunck, R. Angus Smith, and H. E. Roscoe, on the Recent Progress and Present Condition of Manufacturing Chemistry in the South Lancashire District;—Dr. J. Hunt, on Ethno-Climatology; or, the Acclimatization of Man;—Prof. J. Thomson, on Experiments on the Gauging of Water by Triangular Notches;—Dr. A. Voelcker, Report on Field Experiments and Laboratory Researches on the Constituents of Manures essential to cultivated Crops;—Prof. H. Hennessy, Provisional Report on the Present State of our Knowledge respecting the Transmission of Sound-signals during Fogs at Sea;—Dr. P. L. Sclater and F. von Hochstetter, Report on the Present State of our Knowledge of the Birds of the Genus *Apteryx* living in New Zealand;—J. G. Jeffreys, Report of the Results of Deep-sea Dredging in Zetland, with a Notice of several Species of Mollusca new to Science or to the British Isles;—Prof. J. Phillips, Contributions to a Report on the Physical Aspect of the Moon;—W. R. Birt, Contribution to a Report on the Physical Aspect of the Moon;—Dr. Collingwood and Mr. Byerley, Preliminary Report of the Dredging Committee of the Mersey and Dee;—Third Report of the Committee on Steamship Performance;—J. G. Jeffreys, Preliminary Report on the Best Mode of preventing the Ravages of *Teredo* and other Animals in our Ships and Harbours;—R. Mallet, Report on the Experiments made at Holyhead to ascertain the Transit-Velocity of Waves, analogous to Earthquake Waves, through the local Rock Formations;—T. Dobson, on the Explosions in British Coal-Mines during the year 1859;—J. Oldham, Continuation of Report on Steam Navigation at Hull;—Prof. G. Dickie, Brief Summary of a Report on the Flora of the North of Ireland;—Prof. Owen, on the Psychical and Physical Characters of the Mincopies, or Natives of the Andaman Islands, and on the Relations thereby indicated to other Races of Mankind;—Colonel Sykes, Report of the Balloon Committee;—Major-General Sabine, Report on the Repetition of the Magnetic Survey of England;—Interim Report of the Committee for Dredging on the North and East Coasts of Scotland;—W. Fairbairn, on the Resistance of Iron Plates to Statical Pressure and the Force of Impact by Projectiles at High Velocities;—W. Fairbairn, Continuation of Report to determine the effect of Vibratory Action and long-continued Changes of Load upon Wrought-Iron Girders;—Report of the Committee on the Law of Patents;—Prof. H. J. S. Smith, Report on the Theory of Numbers, Part III.

Together with the Transactions of the Sections, Mr. Fairbairn's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE THIRTY-SECOND MEETING at Cambridge, October 1862, *Published at £1.*

CONTENTS:—James Glaisher, Report on Observations of Luminous Meteors, 1861-62;—G. B. Airy, on the Strains in the Interior of Beams;—Archibald Smith and F. J. Evans, Report on the three Reports of the Liverpool Compass Committee;—Report on Tidal Observations on the Humber;—T. Aston, on Rifled Guns and Projectiles

adapted for Attacking Armour-plate Defences;—Extracts, relating to the Observatory at Kew, from a Report presented to the Portuguese Government, by Dr. J. A. de Souza;—H. T. Mennell, Report on the Dredging of the Northumberland Coast and Dogger Bank;—Dr. Cuthbert Collingwood, Report upon the best means of advancing Science through the agency of the Mercantile Marine;—Messrs. Williamson, Wheatstone, Thomson, Miller, Matthiessen, and Jenkin, Provisional Report on Standards of Electrical Resistance;—Preliminary Report of the Committee for investigating the Chemical and Mineralogical Composition of the Granites of Donegal;—Prof. H. Hennessy, on the Vertical Movements of the Atmosphere considered in connection with Storms and Changes of Weather;—Report of Committee on the application of Gauss's General Theory of Terrestrial Magnetism to the Magnetic Variations;—Fleeming Jenkin, on Thermo-electric Currents in Circuits of one Metal;—W. Fairbairn, on the Mechanical Properties of Iron Projectiles at High Velocities;—A. Cayley, Report on the Progress of the Solution of certain Special Problems of Dynamics;—Prof. G. G. Stokes, Report on Double Refraction;—Fourth Report of the Committee on Steamship Performance;—G. J. Symons, on the Fall of Rain in the British Isles in 1860 and 1861;—J. Ball, on Thermometric Observations in the Alps;—J. G. Jeffreys, Report of the Committee for Dredging on the North and East Coasts of Scotland;—Report of the Committee on Technical and Scientific Evidence in Courts of Law;—James Glaisher, Account of Eight Balloon Ascents in 1862;—Prof. H. J. S. Smith, Report on the Theory of Numbers, Part IV.

Together with the Transactions of the Sections, the Rev. Prof. R. Willis's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE THIRTY-THIRD MEETING, at Newcastle-upon-Tyne, August and September 1863, *Published at £1 5s.*

CONTENTS:—Report of the Committee on the Application of Gun-cotton to War-like Purposes;—A. Matthiessen, Report on the Chemical Nature of Alloys;—Report of the Committee on the Chemical and Mineralogical Constitution of the Granites of Donegal, and on the Rocks associated with them;—J. G. Jeffreys, Report of the Committee appointed for exploring the Coasts of Shetland by means of the Dredge;—G. D. Gibb, Report on the Physiological Effects of the Bromide of Ammonium;—C. K. Aken, on the Transmutation of Spectral Rays, Part I.;—Dr. Robinson, Report of the Committee on Fog Signals;—Report of the Committee on Standards of Electrical Resistance;—E. Smith, Abstract of Report by the Indian Government on the Foods used by the Free and Jail Populations in India;—A. Gages, Synthetical Researches on the Formation of Minerals, &c.;—R. Mallet, Preliminary Report on the Experimental Determination of the Temperatures of Volcanic Foci, and of the Temperature, State of Saturation, and Velocity of the issuing Gases and Vapours;—Report of the Committee on Observations of Luminous Meteors;—Fifth Report of the Committee on Steamship Performance;—G. J. Allman, Report on the Present State of our Knowledge of the Reproductive System in the Hydroids;—J. Glaisher, Account of Five Balloon Ascents made in 1863;—P. P. Carpenter, Supplementary Report on the Present State of our Knowledge with regard to the Mollusca of the West Coast of North America;—Prof. Airy, Report on Steam Boiler Explosions;—C. W. Siemens, Observations on the Electrical Resistance and Electrification of some Insulating Materials under Pressures up to 300 Atmospheres;—C. M. Palmer, on the Construction of Iron Ships and the Progress of Iron Shipbuilding on the Tyne, Wear, and Tees;—Messrs. Richardson, Stevenson, and Clapham, on the Chemical Manufactures of the Northern Districts;—Messrs. Sopwith and Richardson, on the Local Manufacture of Lead, Copper, Zinc, Antimony, &c.;—Messrs. Darglish and Forster, on the Magnesian Limestone of Durham;—I. L. Bell, on the Manufacture of Iron in connexion with the Northumberland and Durham Coal-field;—T. Spencer, on the Manufacture of Steel in the Northern District;—Prof. H. J. S. Smith, Report on the Theory of Numbers, Part V.

Together with the Transactions of the Sections, Sir William Armstrong's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE THIRTY-FOURTH MEETING, at Bath, September 1864, *Published at 18s.*

CONTENTS:—Report of the Committee for Observations of Luminous Meteors;—Report of the Committee on the best means of providing for a Uniformity of Weights

and Measures;—T. S. Cobbold, Report of Experiments respecting the Development and Migration of the Entozoa;—B. W. Richardson, Report on the Physiological Action of Nitrite of Amyl;—J. Oldham, Report of the Committee on Tidal Observations;—G. S. Brady, Report on Deep-sea Dredging on the Coasts of Northumberland and Durham in 1864;—J. Glaisher, Account of Nine Balloon Ascents made in 1863 and 1864;—J. G. Jeffreys, Further Report on Shetland Dredgings;—Report of the Committee on the Distribution of the Organic Remains of the North Staffordshire Coal-field;—Report of the Committee on Standards of Electrical Resistance;—G. J. Symons, on the Fall of Rain in the British Isles in 1862 and 1863;—W. Fairbairn, Preliminary Investigation of the Mechanical Properties of the proposed Atlantic Cable.

Together with the Transactions of the Sections, Sir Charles Lyell's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE THIRTY-FIFTH MEETING, at Birmingham, September 1865, *Published at £1 5s.*

CONTENTS:—J. G. Jeffreys, Report on Dredging among the Channel Isles;—F. Buckland, Report on the Cultivation of Oysters by Natural and Artificial Methods;—Report of the Committee for exploring Kent's Cavern;—Report of the Committee on Zoological Nomenclature;—Report on the Distribution of the Organic Remains of the North Staffordshire Coal-field;—Report on the Marine Fauna and Flora of the South Coast of Devon and Cornwall;—Interim Report on the Resistance of Water to Floating and Immersed Bodies;—Report on Observations of Luminous Meteors;—Report on Dredging on the Coast of Aberdeenshire;—J. Glaisher, Account of Three Balloon Ascents;—Interim Report on the Transmission of Sound under Water;—G. J. Symons, on the Rainfall of the British Isles;—W. Fairbairn, on the Strength of Materials considered in relation to the Construction of Iron Ships;—Report of the Gun-Cotton Committee;—A. F. Osler, on the Horary and Diurnal Variations in the Direction and Motion of the Air at Wrotesley, Liverpool, and Birmingham;—B. W. Richardson, Second Report on the Physiological Action of certain of the Amyl Compounds;—Report on further Researches in the Lingulafossils of South Wales;—Report of the Lunar Committee for Mapping the Surface of the Moon;—Report on Standards of Electrical Resistance;—Report of the Committee appointed to communicate with the Russian Government respecting Magnetical Observations at Tiflis;—Appendix to Report on the Distribution of the Vertebrate Remains from the North Staffordshire Coal-field;—H. Woodward, First Report on the Structure and Classification of the Fossil Crustacea;—Prof. H. J. S. Smith, Report on the Theory of Numbers, Part VI.;—Report on the best means of providing for a Uniformity of Weights and Measures, with reference to the interests of Science:—A. G. Findlay, on the Bed of the Ocean;—Prof. A. W. Williamson, on the Composition of Gases evolved by the Bath Spring called King's Bath.

Together with the Transactions of the Sections, Prof. Phillips's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE THIRTY-SIXTH MEETING, at Nottingham, August 1866, *Published at £1 4s.*

CONTENTS:—Second Report on Kent's Cavern, Devonshire;—A. Matthiessen, Preliminary Report on the Chemical Nature of Cast Iron;—Report on Observations of Luminous Meteors;—W. S. Mitchell, Report on the Alum Bay Leaf-bed;—Report on the Resistance of Water to Floating and Immersed Bodies;—Dr. Norris, Report on Muscular Irritability;—Dr. Richardson, Report on the Physiological Action of certain compounds of Amyl and Ethyl;—H. Woodward, Second Report on the Structure and Classification of the Fossil Crustacea;—Second Report on the 'Menevian Group,' and the other Formations at St. David's, Pembrokeshire;—J. G. Jeffreys, Report on Dredging among the Hebrides;—Rev. A. M. Norman, Report on the Coasts of the Hebrides, Part II.;—J. Alder, Notices of some Invertebrata, in connexion with Mr. Jeffreys's Report;—G. S. Brady, Report on the *Ostracoda* dredged amongst the Hebrides;—Report on Dredging in the Moray Firth;—Report on the Transmission of Sound-Signals under Water;—Report of the Lunar Committee;—Report of the Rainfall Committee;—Report on the best means of providing for a Uniformity of Weights and Measures, with reference to the Interests

of Science ;—J. Glaisher, Account of Three Balloon Ascents ;—Report on the Extinct Birds of the Mascarene Islands ;—Report on the Penetration of Ironclad Ships by Steel Shot ;—J. A. Wanklyn, Report on Isomerism among the Alcohols ;—Report on Scientific Evidence in Courts of Law ;—A. L. Adams, Second Report on Maltese Fossiliferous Caves, &c.

Together with the Transactions of the Sections, Mr. Grove's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE THIRTY-SEVENTH MEETING, at Dundee, September 1867, *Published at £1 6s.*

CONTENTS:—Report of the Committee for Mapping the Surface of the Moon ;—Third Report on Kent's Cavern, Devonshire ;—On the present State of the Manufacture of Iron in Great Britain ;—Third Report on the Structure and Classification of the Fossil Crustacea ;—Report on the Physiological Action of the Methyl Compounds ;—Preliminary Report on the Exploration of the Plant-Beds of North Greenland ;—Report of the Steamship Performance Committee ;—On the Meteorology of Port Louis, in the Island of Mauritius ;—On the Construction and Works of the Highland Railway ;—Experimental Researches on the Mechanical Properties of Steel ;—Report on the Marine Fauna and Flora of the South Coast of Devon and Cornwall ;—Supplement to a Report on the Extinct Didine Birds of the Mascarene Islands ;—Report on Observations of Luminous Meteors ;—Fourth Report on Dredging among the Shetland Isles ;—Preliminary Report on the Crustacea, &c., procured by the Shetland Dredging Committee in 1867 ;—Report on the Foraminifera obtained in the Shetland Seas ;—Second Report of the Rainfall Committee ;—Report on the best means of providing for a Uniformity of Weights and Measures, with reference to the interests of Science ;—Report on Standards of Electrical Resistance.

Together with the Transactions of the Sections, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE THIRTY-EIGHTH MEETING, at Norwich, August 1868, *Published at £1 5s.*

CONTENTS:—Report of the Lunar Committee ;—Fourth Report on Kent's Cavern, Devonshire ;—On Puddling Iron ;—Fourth Report on the Structure and Classification of the Fossil Crustacea ;—Report on British Fossil Corals ;—Report on Spectroscopic Investigations of Animal Substances ;—Report of Steamship Performance Committee ;—Spectrum Analysis of the Heavenly Bodies ;—On Stellar Spectrometry ;—Report on the Physiological Action of the Methyl and allied Compounds ;—Report on the Action of Mercury on the Biliary Secretion ;—Last Report on Dredging among the Shetland Isles ;—Reports on the Crustacea, &c., and on the Annelida and Foraminifera from the Shetland Dredgings ;—Report on the Chemical Nature of Cast Iron, Part I. ;—Interim Report on the Safety of Merchant Ships and their Passengers ;—Report on Observations of Luminous Meteors ;—Preliminary Report on Mineral Veins containing Organic Remains ;—Report on the Desirability of Explorations between India and China ;—Report of Rainfall Committee ;—Report on Synthetical Researches on Organic Acids ;—Report on Uniformity of Weights and Measures ;—Report of the Committee on Tidal Observations ;—Report of the Committee on Underground Temperature ;—Changes of the Moon's Surface ;—Report on Polyatomic Cyanides.

Together with the Transactions of the Sections, Dr. Hooker's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE THIRTY-NINTH MEETING, at Exeter, August 1869, *Published at £1 2s.*

CONTENTS:—Report on the Plant-beds of North Greenland ;—Report on the existing knowledge on the Stability, Propulsion, and Seagoing qualities of Ships ;—Report on Steam-boiler Explosions ;—Preliminary Report on the Determination of the Gases existing in Solution in Well-waters ;—The Pressure of Taxation on Real Property ;—On the Chemical Reactions of Light discovered by Prof. Tyndall ;—On Fossils obtained at Kiltorkan Quarry, co. Kilkenny ;—Report of the Lunar Com-

mittee ;—Report on the Chemical Nature of Cast Iron ;—Report on the Marine Fauna and Flora of the South Coast of Devon and Cornwall ;—Report on the Practicability of establishing a 'Close Time' for the Protection of Indigenous Animals ;—Experimental Researches on the Mechanical Properties of Steel ;—Second Report on British Fossil Corals ;—Report of the Committee appointed to get cut and prepared Sections of Mountain-Limestone Corals for Photographing ;—Report on the Rate of Increase of Underground Temperature ;—Fifth Report on Kent's Cavern, Devonshire ;—Report on the Connexion between Chemical Constitution and Physiological Action ;—On Emission, Absorption, and Reflection of Obscure Heat ;—Report on Observations of Luminous Meteors ;—Report on Uniformity of Weights and Measures ;—Report on the Treatment and Utilization of Sewage ;—Supplement to Second Report of the Steamship-Performance Committee ;—Report on Recent Progress in Elliptic and Hyperelliptic Functions ;—Report on Mineral Veins in Carboniferous Limestone and their Organic Contents ;—Notes on the Foraminifera of Mineral Veins and the Adjacent Strata ;—Report of the Rainfall Committee ;—Interim Report on the Laws of the Flow and Action of Water containing Solid Matter in Suspension ;—Interim Report on Agricultural Machinery ;—Report on the Physiological Action of Methyl and Allied Series ;—On the Influence of Form considered in Relation to the Strength of Railway-axles and other portions of Machinery subjected to Rapid Alterations of Strain ;—On the Penetration of Armour-plates with Long Shells of Large Capacity fired obliquely ;—Report on Standards of Electrical Resistance.

Together with the Transactions of the Sections, Prof. Stokes's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE FORTIETH MEETING, at Liverpool, September 1870, *Published at 18s.*

CONTENTS :—Report on Steam-boiler Explosions ;—Report of the Committee on the Hæmatite Iron-ores of Great Britain and Ireland ;—Report on the Sedimentary Deposits of the River Onny ;—Report on the Chemical Nature of Cast Iron ;—Report on the practicability of establishing a 'Close Time' for the protection of Indigenous Animals ;—Report on Standards of Electrical Resistance ;—Sixth Report on Kent's Cavern ;—Third Report on Underground Temperature ;—Second Report of the Committee appointed to get cut and prepared Sections of Mountain-Limestone Corals ;—Second Report on the Stability, Propulsion, and Seagoing Qualities of Ships ;—Report on Earthquakes in Scotland ;—Report on the Treatment and Utilization of Sewage ;—Report on Observations of Luminous Meteors, 1869–70 ;—Report on Recent Progress in Elliptic and Hyperelliptic Functions ;—Report on Tidal Observations ;—On a new Steam-power Meter ;—Report on the Action of the Methyl and Allied Series ;—Report of the Rainfall Committee ;—Report on the Heat generated in the Blood in the Process of Arterialization ;—Report on the best means of providing for Uniformity of Weights and Measures.

Together with the Transactions of the Sections, Prof. Huxley's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE FORTY-FIRST MEETING, at Edinburgh, August 1871, *Published at 16s.*

CONTENTS :—Seventh Report on Kent's Cavern ;—Fourth Report on Underground Temperature ;—Report on Observations of Luminous Meteors, 1870–71 ;—Fifth Report on the Structure and Classification of the Fossil Crustacea ;—Report of the Committee appointed for the purpose of urging on Her Majesty's Government the expediency of arranging and tabulating the results of the approaching Census in the three several parts of the United Kingdom in such a manner as to admit of ready and effective comparison ;—Report of the Committee appointed for the purpose of Superintending the Publication of Abstracts of Chemical Papers ;—Report of the Committee for discussing Observations of Lunar Objects suspected of change ;—Second Provisional Report on the Thermal Conductivity of Metals ;—Report on the Rainfall of the British Isles ;—Third Report on the British Fossil Corals ;—Report on the Heat generated in the Blood during the Process of Arterialization ;—Report of the Committee appointed to consider the subject of Physiological

Experimentation;—Report on the Physiological Action of Organic Chemical Compounds;—Report of the Committee appointed to get cut and prepared Sections of Mountain-Limestone Corals;—Second Report on Steam-Boiler Explosions;—Report on the Treatment and Utilization of Sewage;—Report on promoting the Foundation of Zoological Stations in different parts of the World;—Preliminary Report on the Thermal Equivalents of the Oxides of Chlorine;—Report on the practicability of establishing a 'Close Time' for the protection of Indigenous Animals;—Report on Earthquakes in Scotland;—Report on the best means of providing for a Uniformity of Weights and Measures;—Report on Tidal Observations.

Together with the Transactions of the Sections, Sir William Thomson's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE FORTY-SECOND MEETING, at Brighton, August 1872, *Published at £1 4s.*

CONTENTS:—Report on the Gaussian Constants for the Year 1829;—Second Supplementary Report on the Extinct Birds of the Mascarene Islands;—Report of the Committee for Superintending the Monthly Reports of the Progress of Chemistry;—Report of the Committee on the best means of providing for a Uniformity of Weights and Measures;—Eighth Report on Kent's Cavern;—Report on promoting the Foundation of Zoological Stations in different parts of the World;—Fourth Report on the Fauna of South Devon;—Preliminary Report of the Committee appointed to Construct and Print Catalogues of Spectral Rays arranged upon a Scale of Wavenumbers;—Third Report on Steam-Boiler Explosions;—Report on Observations of Luminous Meteors, 1871-72;—Experiments on the Surface-friction experienced by a Plane moving through Water;—Report of the Committee on the Antagonism between the Action of Active Substances;—Fifth Report on Underground Temperature;—Preliminary Report of the Committee on Siemens's Electrical-Resistance Pyrometer;—Fourth Report on the Treatment and Utilization of Sewage;—Interim Report of the Committee on Instruments for Measuring the Speed of Ships and Currents;—Report on the Rainfall of the British Isles;—Report of the Committee on a Geographical Exploration of the Country of Moab;—Sur l'élimination des Fonctions Arbitraires;—Report on the Discovery of Fossils in certain remote parts of the North-western Highlands;—Report of the Committee on Earthquakes in Scotland;—Fourth Report on Carboniferous-Limestone Corals;—Report of the Committee to consider the mode in which new Inventions and Claims for Reward in respect of adopted Inventions are examined and dealt with by the different Departments of Government;—Report of the Committee for discussing Observations of Lunar Objects suspected of change;—Report on the Mollusca of Europe;—Report of the Committee for investigating the Chemical Constitution and Optical Properties of Essential Oils;—Report on the practicability of establishing a 'Close Time' for the preservation of Indigenous Animals;—Sixth Report on the Structure and Classification of Fossil Crustacea;—Report of the Committee appointed to organize an Expedition for observing the Solar Eclipse of Dec. 12, 1871;—Preliminary Report of a Committee on Terato-embryological Inquiries;—Report on Recent Progress in Elliptic and Hyperelliptic Functions;—Report on Tidal Observations;—On the Brighton Waterworks;—On Amsler's Planimeter.

Together with the Transactions of the Sections, Dr. Carpenter's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE FORTY-THIRD MEETING, at Bradford, September 1873, *Published at £1 5s.*

CONTENTS:—Report of the Committee on Mathematical Tables;—Observations on the Application of Machinery to the Cutting of Coal in Mines;—Concluding Report on the Maltese Fossil Elephants;—Report of the Committee for ascertaining the Existence in different parts of the United Kingdom of any Erratic Blocks or Boulders;—Fourth Report on Earthquakes in Scotland;—Ninth Report on Kent's Cavern;—On the Flint and Chert Implements found in Kent's Cavern;—Report of the Committee for Investigating the Chemical Constitution and Optical Properties of Essential Oils;—Report of Inquiry into the Method of making Gold-assays;

—Fifth Report on the Selection and Nomenclature of Dynamical and Electrical Units;—Report of the Committee on the Labyrinthodonts of the Coal-measures;—Report of the Committee appointed to construct and print Catalogues of Spectral Rays;—Report of the Committee appointed to explore the Settle Caves;—Sixth Report on Underground Temperature;—Report on the Rainfall of the British Isles;—Seventh Report on Researches in Fossil Crustacea;—Report on Recent Progress in Elliptic and Hyperelliptic Functions;—Report on the desirability of establishing a 'Close Time' for the preservation of Indigenous Animals;—Report on Luminous Meteors;—On the Visibility of the Dark Side of Venus;—Report of the Committee for the Foundation of Zoological Stations in different parts of the World;—Second Report of the Committee for collecting Fossils from North-western Scotland;—Fifth Report on the Treatment and Utilization of Sewage;—Report of the Committee on Monthly Reports of the Progress of Chemistry;—On the Bradford Waterworks;—Report on the possibility of Improving the Methods of Instruction in Elementary Geometry;—Interim Report of the Committee on Instruments for Measuring the Speed of Ships, &c.;—Report of the Committee for Determinating High Temperatures by means of the Refrangibility of Light evolved by Fluid or Solid Substances;—On a Periodicity of Cyclones and Rainfall in connexion with Sunspot Periodicity;—Fifth Report on the Structure of Carboniferous-Limestone Corals;—Report of the Committee on preparing and publishing brief forms of Instructions for Travellers, Ethnologists &c.;—Preliminary Note from the Committee on the Influence of Forests on the Rainfall;—Report of the Sub-Wealden Exploration Committee;—Report of the Committee on Machinery for obtaining a Record of the Roughness of the Sea and Measurement of Waves near shore;—Report on Science Lectures and Organization;—Second Report on Science Lectures and Organization.

Together with the Transactions of the Sections, Prof. A. W. Williamson's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE FORTY-FOURTH MEETING, at Belfast, August 1874, *Published at £1 5s.*

CONTENTS:—Tenth Report on Kent's Cavern;—Report for investigating the Chemical Constitution and Optical Properties of Essential Oils;—Second Report of the Sub-Wealden Exploration Committee;—On the Recent Progress and Present State of Systematic Botany;—Report of the Committee for investigating the Nature of Intestinal Secretion;—Report of the Committee on the Teaching of Physics in Schools;—Preliminary Report for investigating Isomeric Cresols and their Derivatives;—Third Report of the Committee for collecting Fossils from localities in North-western Scotland;—Report on the Rainfall of the British Isles;—On the Belfast Harbour;—Report of Inquiry into the Method of making Gold-assays;—Report of a Committee on Experiments to determine the Thermal Conductivities of certain Rocks;—Second Report on the Exploration of the Settle Caves;—On the Industrial uses of the Upper Bann River;—Report of the Committee on the Structure and Classification of the Labyrinthodonts;—Second Report of the Committee for recording the position, height above the sea, lithological characters, size, and origin of the Erratic Blocks of England and Wales, &c.;—Sixth Report on the Treatment and Utilization of Sewage;—Report on the Anthropological Notes and Queries for the use of Travellers;—On Cyclone and Rainfall Periodicities;—Fifth Report on Earthquakes in Scotland;—Report of the Committee appointed to prepare and print Tables of Wave-numbers;—Report of the Committee for testing the new Pyrometer of Mr. Siemens;—Report to the Lords Commissioners of the Admiralty on Experiments for the Determination of the Frictional Resistance of Water on a Surface &c.;—Second Report for the Selection and Nomenclature of Dynamical and Electrical Units;—On Instruments for measuring the Speed of Ships;—Report of the Committee on the possibility of establishing a 'Close Time' for the Protection of Indigenous Animals;—Report of the Committee to inquire into the economic effects of Combinations of Labourers and Capitalists;—Preliminary Report on Dredging on the Coasts of Durham and North Yorkshire;—Report on Luminous Meteors;—Report on the best means of providing for a Uniformity of Weights and Measures.

Together with the Transactions of the Sections, Prof. John Tyndall's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE FORTY-FIFTH MEETING, at Bristol, August 1875, Published at £1 5s. (Out of Print.)

CONTENTS:—Eleventh Report on Kent's Cavern;—Seventh Report on Underground Temperature;—Report on the Zoological Station at Naples;—Report of a Committee appointed to inquire into the Methods employed in the Estimation of Potash and Phosphoric Acid in Commercial Products;—Report on the present state of our Knowledge of the Crustacea;—Second Report on the Thermal Conductivities of certain Rocks;—Preliminary Report of the Committee for extending the Observations on the Specific Volumes of Liquids;—Sixth Report on Earthquakes in Scotland;—Seventh Report on the Treatment and Utilization of Sewage;—Report of the Committee for furthering the Palestine Explorations;—Third Report of the Committee for recording the position, height above the sea, lithological characters, size, and origin of the Erratic Blocks of England and Wales, &c.;—Report of the Rainfall Committee;—Report of the Committee for investigating Isomeric Cresols and their Derivatives;—Report of the Committee for investigating the Circulation of the Underground Waters in the New Red Sandstone and Permian Formations of England;—On the Steering of Screw-Steamers;—Second Report of the Committee on Combinations of Capital and Labour;—Report on the Method of making Gold-assays;—Eighth Report on Underground Temperature;—Tides in the River Mersey;—Sixth Report of the Committee on the Structure of Carboniferous Corals;—Report of the Committee appointed to explore the Settle Caves;—On the River Avon (Bristol), its Drainage-Area, &c.;—Report of the Committee on the possibility of establishing a 'Close Time' for the Protection of Indigenous Animals;—Report of the Committee appointed to superintend the Publication of the Monthly Reports of the Progress of Chemistry;—Report on Dredging off the Coasts of Durham and North Yorkshire in 1874;—Report on Luminous Meteors;—On the Analytical Forms called Trees;—Report of the Committee on Mathematical Tables;—Report of the Committee on Mathematical Notation and Printing;—Second Report of the Committee for investigating Intestinal Secretion;—Third Report of the Sub-Wealden Exploration Committee.

Together with the Transactions of the Sections, Sir John Hawkshaw's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE FORTY-SIXTH MEETING, at Glasgow, September 1876, Published at £1 5s.

CONTENTS:—Twelfth Report on Kent's Cavern;—Report on Improving the Methods of Instruction in Elementary Geometry;—Results of a Comparison of the British-Association Units of Electrical Resistance;—Third Report on the Thermal Conductivities of certain Rocks;—Report of the Committee on the practicability of adopting a Common Measure of Value in the Assessment of Direct Taxation;—Report of the Committee for testing experimentally Ohm's Law;—Report of the Committee on the possibility of establishing a 'Close Time' for the Protection of Indigenous Animals;—Report of the Committee on the Effect of Propellers on the Steering of Vessels;—On the Investigation of the Steering Qualities of Ships;—Seventh Report on Earthquakes in Scotland;—Report on the present state of our Knowledge of the Crustacea;—Second Report of the Committee for investigating the Circulation of the Underground Waters in the New Red Sandstone and Permian Formations of England;—Fourth Report of the Committee on the Erratic Blocks of England and Wales, &c.;—Fourth Report of the Committee on the Exploration of the Settle Caves (Victoria Cave);—Report on Observations of Luminous Meteors, 1875-76;—Report on the Rainfall of the British Isles, 1875-76;—Ninth Report on Underground Temperature;—Nitrous Oxide in the Gaseous and Liquid States;—Eighth Report on the Treatment and Utilization of Sewage;—Improved Investigations on the Flow of Water through Orifices, with Objections to the modes of treatment commonly adopted;—Report of the Anthropometric Committee;—On Cyclone and Rainfall Periodicities in connexion with the Sun-spot Periodicity;—Report of the Committee for determining the Mechanical Equivalent of Heat;—Report of the Committee on Tidal Observations;—Third Report of the Committee on the Conditions of Intestinal Secretion and Movement;—Report of the Committee for collecting and suggesting subjects for Chemical Research.

Together with the Transactions of the Sections, Dr. T. Andrews's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE FORTY-SEVENTH MEETING, at Plymouth, August 1877, Published at £1 4s.

CONTENTS:—Thirteenth Report on Kent's Cavern;—Second and Third Reports on the Methods employed in the estimation of Potash and Phosphoric Acid in Commercial Products;—Report on the present state of our Knowledge of the Crustacea (Part III.);—Third Report on the Circulation of the Underground Waters in the New Red Sandstone and Permian Formations of England;—Fifth Report on the Erratic Blocks of England, Wales, and Ireland;—Fourth Report on the Thermal Conductivities of certain Rocks;—Report on Observations of Luminous Meteors, 1876-77;—Tenth Report on Underground Temperature;—Report on the Effect of Propellers on the Steering of Vessels;—Report on the possibility of establishing a 'Close Time' for the Protection of Indigenous Animals;—Report on some Double Compounds of Nickel and Cobalt;—Fifth Report on the Exploration of the Settle Caves (Victoria Cave);—Report on the Datum Level of the Ordnance Survey of Great Britain;—Report on the Zoological Station at Naples;—Report of the Anthropometric Committee;—Report on the Conditions under which Liquid Carbonic Acid exists in Rocks and Minerals.

Together with the Transactions of the Sections, Prof. Allen Thomson's Address and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE FORTY-EIGHTH MEETING, at Dublin, August 1878, Published at £1 4s.

CONTENTS:—Catalogue of the Oscillation-Frequencies of Solar Rays;—Report on Mr. Babbage's Analytical Machine;—Third Report of the Committee for determining the Mechanical Equivalent of Heat;—Report of the Committee for arranging for the taking of certain Observations in India, and Observations on Atmospheric Electricity at Madeira;—Report on the commencement of Secular Experiments upon the Elasticity of Wires;—Report on the Chemistry of some of the lesser-known Alkaloids, especially Veratria and Bebeerine;—Report on the best means for the Development of Light from Coal-Gas;—Fourteenth Report on Kent's Cavern;—Report on the Fossils in the North-west Highlands of Scotland;—Fifth Report on the Thermal Conductivities of certain Rocks;—Report on the possibility of establishing a 'Close Time' for the Protection of Indigenous Animals;—Report on the occupation of a Table at the Zoological Station at Naples;—Report of the Anthropometric Committee;—Report on Patent Legislation;—Report on the Use of Steel for Structural Purposes;—Report on the Geographical Distribution of the Chiroptera;—Recent Improvements in the Port of Dublin;—Report on Mathematical Tables;—Eleventh Report on Underground Temperature;—Report on the Exploration of the Fermanagh Caves;—Sixth Report on the Erratic Blocks of England, Wales, and Ireland;—Report on the present state of our Knowledge of the Crustacea (Part IV.);—Report on two Caves in the neighbourhood of Tenby;—Report on the Stationary Tides in the English Channel and in the North Sea, &c.;—Second Report on the Datum-level of the Ordnance Survey of Great Britain;—Report on instruments for measuring the Speed of Ships;—Report of Investigations into a Common Measure of Value in Direct Taxation;—Report on Sunspots and Rainfall;—Report on Observations of Luminous Meteors;—Sixth Report on the Exploration of the Settle Caves (Victoria Cave);—Report on the Kentish Boring Exploration;—Fourth Report on the Circulation of Underground Waters in the Jurassic, New Red Sandstone, and Permian Formations, with an Appendix on the Filtration of Water through Triassic Sandstone;—Report on the Effect of Propellers on the Steering of Vessels.

Together with the Transactions of the Sections, Mr. Spottiswoode's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE FORTY-NINTH MEETING, at Sheffield, August 1879, Published at £1 4s.

CONTENTS:—Report on the commencement of Secular Experiments upon the Elasticity of Wires;—Fourth Report of the Committee for determining the Mechanical Equivalent of Heat;—Report of the Committee for endeavouring to procure reports on the Progress of the Chief Branches of Mathematics and Physics;—Twelfth

Report on Underground Temperature;—Report on Mathematical Tables;—Sixth Report on the Thermal Conductivities of certain Rocks;—Report on Observations of Atmospheric Electricity at Madeira;—Report on the Calculation of Tables of the Fundamental Invariants of Algebraic Forms;—Report on the Calculation of Sun-Heat Coefficients;—Second Report on the Stationary Tides in the English Channel and in the North Sea, &c.;—Report on Observations of Luminous Meteors;—Report on the question of Improvements in Astronomical Clocks;—Report of the Committee for improving an Instrument for detecting the presence of Fire-damp in Mines;—Report on the Chemistry of some of the lesser-known Alkaloids, especially Veratria and Beeberine;—Seventh Report on the Erratic Blocks of England, Wales, and Ireland;—Fifteenth Report on Kent's Cavern;—Report on certain Caves in Borneo;—Fifth Report on the Circulation of Underground Waters in the Jurassic, Red Sandstone, and Permian Formations of England;—Report on the Tertiary (Miocene) Flora, &c., of the Basalt of the North of Ireland;—Report on the possibility of Establishing a 'Close Time' for the Protection of Indigenous Animals;—Report on the Marine Zoology of Devon and Cornwall;—Report on the Occupation of a Table at the Zoological Station at Naples;—Report on Excavations at Portstewart and elsewhere in the North of Ireland;—Report of the Anthropometric Committee;—Report on the Investigation of the Natural History of Socotra;—Report on Instruments for measuring the Speed of Ships;—Third Report on the Datum-level of the Ordnance Survey of Great Britain;—Second Report on Patent Legislation;—On Self-acting Intermittent Siphons and the conditions which determine the commencement of their Action;—On some further Evidence as to the Range of the Palæozoic Rocks beneath the South-east of England;—Hydrography, Past and Present.

Together with the Transactions of the Sections, Prof. Allman's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE FIFTIETH MEETING, at Swansea, August and September 1880, Published at £1 4s.

CONTENTS:—Report on the Measurement of the Lunar Disturbance of Gravity;—Thirteenth Report on Underground Temperature;—Report of the Committee for devising and constructing an improved form of High Insulation Key for Electrometer Work;—Report on Mathematical Tables;—Report on the Calculation of Tables of the Fundamental Invariants of Algebraic Forms;—Report on Observations of Luminous Meteors;—Report on the question of Improvements in Astronomical Clocks;—Report on the commencement of Secular Experiments on the Elasticity of Wires;—Sixteenth and concluding Report on Kent's Cavern;—Report on the mode of reproduction of certain species of Ichthyosaurus from the Lias of England and Würtemberg;—Report on the Carboniferous Polyzoa;—Report on the 'Geological Record';—Sixth Report on the Circulation of the Underground Waters in the Permian, New Red Sandstone, and Jurassic Formations of England, and the Quantity and Character of the Water supplied to towns and districts from these formations;—Second Report on the Tertiary (Miocene) Flora, &c., of the Basalt of the North of Ireland;—Eighth Report on the Erratic Blocks of England, Wales, and Ireland;—Report on an Investigation for the purpose of fixing a Standard of White Light;—Report of the Anthropometric Committee;—Report on the Influence of Bodily Exercise on the Elimination of Nitrogen;—Second Report on the Marine Zoology of South Devon;—Report on the Occupation of a Table at the Zoological Station at Naples;—Report on accessions to our knowledge of the Chiroptera during the past two years (1878–80);—Preliminary Report on the accurate measurement of the specific inductive capacity of a good Sprengel Vacuum, and the specific resistance of gases at different pressures;—Comparison of Curves of the Declination Magnetographs at Kew, Stonyhurst, Coimbra, Lisbon, Vienna, and St. Petersburg;—First Report on the Caves of the South of Ireland;—Report on the Investigation of the Natural History of Socotra;—Report on the German and other systems of teaching the Deaf to speak;—Report of the Committee for considering whether it is important that H.M. Inspectors of Elementary Schools should be appointed with reference to their ability for examining in the scientific specific subjects of the Code in addition to other matters;—On the Anthracite Coal and Coalfield of South Wales;—Report on the present state of our knowledge of Crustacea (Part V.);—Report on the best means for the Development of Light from Coal-gas of different qualities (Part II.);—Report

on Palæontological and Zoological Researches in Mexico;—Report on the possibility of establishing a 'Close Time' for Indigenous Animals;—Report on the present state of our knowledge of Spectrum Analysis;—Report on Patent Legislation;—Preliminary Report on the present Appropriation of Wages, &c.;—Report on the present state of knowledge of the application of Quadratures and Interpolation to Actual Data;—The French Deep-sea Exploration in the Bay of Biscay;—Third Report on the Stationary Tides in the English Channel and in the North Sea, &c.;—List of Works on the Geology, Mineralogy, and Palæontology of Wales (to the end of 1873);—On the recent Revival in Trade.

Together with the Transactions of the Sections, Dr. A. C. Ramsay's Address, and Recommendations of the Association and its Committees.

PROCEEDINGS OF THE FIFTY-FIRST MEETING, at York, August and September 1881, *Published at £1 4s.*

CONTENTS:—Report on the Calculation of Tables of the Fundamental Invariants of Algebraic Forms;—Report on Recent Progress in Hydrodynamics (Part I.);—Report on Meteoric Dust;—Second Report on the Calculation of Sun-heat Coefficients;—Fourteenth Report on Underground Temperature;—Report on the Measurement of the Lunar Disturbance of Gravity;—Second Report on an Investigation for the purpose of fixing a Standard of White Light;—Final Report on the Thermal Conductivities of certain Rocks;—Report on the manner in which Rudimentary Science should be taught, and how Examinations should be held therein, in Elementary Schools;—Third Report on the Tertiary Flora of the North of Ireland;—Report on the Method of Determining the Specific Refraction of Solids from their Solutions;—Fourth Report on the Stationary Tides in the English Channel and in the North Sea, &c.;—Second Report on Fossil Polyzoa;—Report on the Maintenance of the Scottish Zoological Station;—Report on the Occupation of a Table at the Zoological Station at Naples;—Report on the Migration of Birds;—Report on the Natural History of Socotra;—Report on the Natural History of Timor-laut;—Report on the Marine Fauna of the Southern Coast of Devon and Cornwall;—Report on the Earthquake Phenomena of Japan;—Ninth Report on the Erratic Blocks of England, Wales, and Ireland;—Second Report on the Caves of the South of Ireland;—Report on Patent Legislation;—Report of the Anthropometric Committee;—Report on the Appropriation of Wages, &c.;—Report on Observations of Luminous Meteors;—Report on Mathematical Tables;—Seventh Report on the Circulation of Underground Waters in the Jurassic, New Red Sandstone, and Permian Formations of England, and the Quality and Quantity of the Water supplied to Towns and Districts from these Formations;—Report on the present state of our Knowledge of Spectrum Analysis;—Interim Report of the Committee for constructing and issuing practical Standards for use in Electrical Measurements;—On some new Theorems on Curves of Double Curvature;—Observations of Atmospheric Electricity at the Kew Observatory during 1880;—On the Arrestation of Infusorial Life by Solar Light;—On the Effects of Oceanic Currents upon Climates;—On Magnetic Disturbances and Earth Currents;—On some Applications of Electric Energy to Horticultural and Agricultural purposes;—On the Pressure of Wind upon a Fixed Plane Surface;—On the Island of Socotra;—On some of the Developments of Mechanical Engineering during the last Half-Century.

Together with the Transactions of the Sections, Sir John Lubbock's Address, and Recommendations of the Association and its Committees.

REPORT OF THE FIFTY-SECOND MEETING, at Southampton, August 1882, *Published at £1 4s.*

CONTENTS:—Report on the Calculation of Tables of Fundamental Invariants of Binary Quantics;—Report (provisional) of the Committee for co-operating with the Meteorological Society of the Mauritius in their proposed publication of Daily Synoptic Charts of the Indian Ocean from the year 1861;—Report of the Committee appointed for fixing a Standard of White Light;—Report on Recent Progress in Hydrodynamics (Part II.);—Report of the Committee for constructing and issuing practical Standards for use in Electrical Measurements;—Fifteenth Report on Underground Temperature, with Summary of the Results contained in the Fifteen Reports

of the Underground Temperature Committee;—Report on Meteoric Dust;—Second Report on the Measurement of the Lunar Disturbance of Gravity;—Report on the present state of our Knowledge of Spectrum Analysis;—Report on the Investigation by means of Photography of the Ultra-Violet Spark Spectra emitted by Metallic Elements, and their combinations under varying conditions;—Report of the Committee for preparing a new Series of Tables of Wave-lengths of the Spectra of the Elements;—Report on the Methods employed in the Calibration of Mercurial Thermometers;—Second Report on the Earthquake Phenomena of Japan;—Eighth Report on the Circulation of the Underground Waters in the Permeable Formations of England, and the Quality and Quantity of the Water supplied to various Towns and Districts from these Formations;—Report on the Conditions under which ordinary Sedimentary Materials may be converted into Metamorphic Rocks;—Report on Explorations in Caves of Carboniferous Limestone in the South of Ireland;—Report on the Preparation of an International Geological Map of Europe;—Tenth Report on the Erratic Blocks of England, Wales and Ireland;—Report on Fossil Polyzoa (Jurassic Species—British Area only);—Preliminary Report on the Flora of the 'Halifax Hard Bed,' Lower Coal Measures;—Report on the Influence of Bodily Exercise on the Elimination of Nitrogen;—Report of the Committee appointed for obtaining Photographs of the Typical Races in the British Isles;—Preliminary Report on the Ancient Earthwork in Epping Forest known as the Loughton Camp;—Second Report on the Natural History of Timor-laut;—Report of the Committee for carrying out the recommendations of the Anthropometric Committee of 1880, especially as regards the anthropometry of children and of females, and the more complete discussion of the collected facts;—Report on the Natural History of Socotra and the adjacent Highlands of Arabia and Somali Land;—Report on the Maintenance of the Scottish Zoological Station;—Report on the Migration of Birds;—Report on the Occupation of a Table at the Zoological Station at Naples;—Report on the Survey of Eastern Palestine;—Final Report on the Appropriation of Wages, &c.;—Report on the working of the revised New Code, and of other legislation affecting the teaching of Science in Elementary Schools;—Report on Patent Legislation;—Report of the Committee for determining a Gauge for the manufacture of various small Screws;—Report on the best means of ascertaining the Effective Wind Pressure to which buildings and structures are exposed;—On the Boiling Points and Vapour Tension of Mercury, of Sulphur, and of some Compounds of Carbon, determined by means of the Hydrogen Thermometer;—On the Method of Harmonic Analysis used in deducing the Numerical Values of the Tides of long period, and on a Misprint in the Tidal Report for 1872;—List of Works on the Geology and Palæontology of Oxfordshire, of Berkshire, and of Buckinghamshire;—Notes on the oldest Records of the Sea-Route to China from Western Asia;—The Deserts of Africa and Asia;—State of Crime in England, Scotland, and Ireland in 1880;—On the Treatment of Steel for the Construction of Ordnance, and other purposes;—The Channel Tunnel;—The Forth Bridge.

Together with the Transactions of the Sections, Dr. C. W. Siemens's Address, and Recommendations of the Association and its Committees.

REPORT OF THE FIFTY-THIRD MEETING, at Southport, September 1883, *Published at £1 4s.*

CONTENTS:—Report of the Committee for constructing and issuing practical Standards for use in Electrical Measurements;—Sixteenth Report on Underground Temperature;—Report on the best Experimental Methods that can be used in observing Total Solar Eclipses;—Report on the Harmonic Analysis of Tidal Observations;—Report of the Committee for co-operating with the Meteorological Society of the Mauritius in their proposed publication of Daily Synoptic Charts of the Indian Ocean from the year 1861;—Report on Mathematical Tables;—Report of the Committee for co-operating with the Scottish Meteorological Society in making Meteorological Observations on Ben Nevis;—Report on Meteoric Dust;—Report of the Committee appointed for fixing a Standard of White Light;—Report on Chemical Nomenclature;—Report on the investigation by means of Photography of the Ultra-Violet Spark Spectra emitted by Metallic Elements, and their combinations under varying conditions;—Report on Isomeric Naphthalene Derivatives;—Report on Explorations in Caves in the Carboniferous Limestone in the South of Ireland;—Report on the Exploration of Raygill Fissure, Yorkshire;—Eleventh Report on the

Erratic Blocks of England, Wales, and Ireland ;—Ninth Report on the Circulation of the Underground Waters in the Permeable Formations of England, and the Quality and Quantity of the Water supplied to various Towns and Districts from these Formations ;—Report on the Fossil Plants of Halifax ;—Fourth Report on Fossil Polyzoa ;—Fourth Report on the Tertiary Flora of the North of Ireland ;—Report on the Earthquake Phenomena of Japan ;—Report on the Fossil Phyllopoda of the Palæozoic Rocks ;—Third Report on the Natural History of Timor Laut ;—Report on the Natural History of Socotra and the adjacent Highlands of Arabia and Somali Land ;—Report on the Exploration of Kilima-njaro and the adjoining mountains of Eastern Equatorial Africa ;—Report on the Migration of Birds ;—Report on the Maintenance of the Scottish Zoological Station ;—Report on the Occupation of a Table at the Zoological Station at Naples ;—Report on the Influence of Bodily Exercise on the Elimination of Nitrogen ;—Report on the Ancient Earthwork in Epping Forest, known as the 'Loughton' or 'Cowper's' Camp ;—Final Report of the Anthropometric Committee ;—Report of the Committee for defining the Facial Characteristics of the Races and Principal Crosses in the British Isles, and obtaining Illustrative Photographs ;—Report on the Survey of Eastern Palestine ;—Report on the workings of the proposed revised New Code, and of other legislation affecting the teaching of Science in Elementary Schools ;—Report on Patent Legislation ;—Report of the Committee for determining a Gauge for the manufacture of various small Screws ;—Report of the 'Local Scientific Societies' Committee ;—On some results of photographing the Solar Corona without an Eclipse ;—On Lamé's Differential Equation ;—Recent Changes in the Distribution of Wealth in relation to the Incomes of the Labouring Classes ;—On the Mersey Tunnel ;—On Manganese Bronze ;—Nest Gearing.

Together with the Transactions of the Sections, Professor Cayley's Address, and Recommendations of the Association and its Committees.

REPORT OF THE FIFTY-FOURTH MEETING, at Montreal, August and September, 1884, *Published at 1l. 4s.*

CONTENTS :—Report of the Committee for considering and advising on the best means for facilitating the adoption of the Metric System of Weights and Measures in Great Britain ;—Report of the Committee for considering the best methods of recording the direct intensity of Solar Radiation ;—Report of the Committee for constructing and issuing practical Standards for use in Electrical Measurements ;—Report of the Committee for co-operating with the Meteorological Society of the Mauritius, in their proposed publication of Daily Synoptic Charts of the Indian Ocean from the year 1861 ;—Second Report on the Harmonic Analysis of Tidal Observations ;—Report of the Committee for co-operating with Mr. E. J. Lowe in his project of establishing a Meteorological Observatory near Chepstow on a permanent and scientific basis ;—Report of the Committee for co-operating with the Directors of the Ben Nevis Observatory in making Meteorological Observations on Ben Nevis ;—Report of the Committee for reducing and tabulating the Tidal Observations in the English Channel, made with the Dover Tide-gauge, and for connecting them with Observations made on the French Coast ;—Fourth Report on Meteoric Dust ;—Second Report on Chemical Nomenclature ;—Report on Isomeric Naphthalene Derivatives ;—Second Report on the Fossil Phyllopoda of the Palæozoic Rocks ;—Tenth Report on the Circulation of Underground Waters in the Permeable Formations of England and Wales, and the Quantity and Character of the Water supplied to various Towns and Districts from these Formations ;—Fifth and last Report on Fossil Polyzoa ;—Twelfth Report on the Erratic Blocks of England, Wales, and Ireland ;—Report upon the National Geological Surveys of Europe ;—Report on the Rate of Erosion of the Sea-coasts of England and Wales, and the Influence of the Artificial Abstraction of Shingle or other material in that action ;—Report on the Exploration of the Raygill Fissure in Lothersdale, Yorkshire ;—Fourth Report on the Earthquake Phenomena of Japan ;—Report on the occupation of a Table at the Zoological Station at Naples ;—Fourth Report on the Natural History of Timor Laut ;—Report on the Influence of Bodily Exercise on the Elimination of Nitrogen ;—Report on the Migration of Birds ;—Report on the Preparation of a Bibliography of certain groups of Invertebrata ;—Report on the Exploration of Kilima-njaro, and the adjoining mountains of Eastern Equatorial Africa ;—Report on the Survey of Eastern Palestine ;—Report of the Committee for defraying the expenses of completing the Preparation of the final Report of the Anthropometric Committee ;—Report on the

teaching of Science in Elementary Schools;—Report of the Committee for determining a Gauge for the manufacture of the various small Screws used in Telegraphic and Electrical Apparatus, in Clockwork, and for other analogous purposes;—Report on Patent Legislation;—Report of the Committee for defining the Facial Characteristics of the Races and Principal Crosses in the British Isles, and obtaining Illustrative Photographs with a view to their publication;—Report on the present state of our knowledge of Spectrum Analysis;—Report of the Committee for preparing a new series of Wave-length Tables of the Spectra of the Elements;—On the Connection between Sunspots and Terrestrial Phenomena;—On the Seat of the Electromotive Forces in the Voltaic Cell;—On the Archæan Rocks of Great Britain;—On the Concordance of the Mollusca inhabiting both sides of the North Atlantic and the intermediate Seas;—On the Characteristics of the North American Flora;—On the Theory of the Steam Engine;—Improvements in Coast Signals, with Supplementary Remarks on the New Eddystone Lighthouse;—On American Permanent Way.

Together with the Transactions of the Sections, Lord Rayleigh's Address, and Recommendations of the Association and its Committees.

REPORT OF THE FIFTY-FIFTH MEETING, at Aberdeen, September 1885, *Published at £1 4s.*

CONTENTS:—Report of the Committee for constructing and issuing practical Standards for use in Electrical Measurements;—Report of the Committee for promoting Tidal Observations in Canada;—Fifth Report on Meteoric Dust;—Third Report on the Harmonic Analysis of Tidal Observations;—Report of the Committee for co-operating with the Meteorological Society of the Mauritius in their proposed publication of Daily Synoptic Charts of the Indian Ocean from the year 1861;—Report of the Committee for reducing and tabulating the Tidal Observations in the English Channel, made with the Dover Tide-gauge, and for connecting them with Observations made on the French Coast;—Report on Standards of White Light;—Report of the Committee for co-operating with Mr. E. J. Lowe in his project of establishing a Meteorological Observatory near Chepstow on a permanent and scientific basis;—Report on the best means of Comparing and Reducing Magnetic Observations;—Report of the Committee for co-operating with the Scottish Meteorological Society in making Meteorological Observations on Ben Nevis;—Seventeenth Report on Underground Temperature;—Report on Electrical Theories;—Second Report of the Committee for considering the best methods of recording the direct intensity of Solar Radiation;—Report on Optical Theories;—Report of the Committee for investigating certain Physical Constants of Solution, especially the Expansion of Saline Solutions;—Third Report on Chemical Nomenclature;—Report of the Committee for the Investigation by means of Photography of the Ultra-Violet Spark Spectra emitted by Metallic Elements and their Combinations under varying conditions;—Report of the Committee for investigating the subject of Vapour Pressures and Refractive Indices of Salt Solutions;—Report of the Committee for preparing a new series of Wave-length Tables of the Spectra of the Elements and Compounds;—Thirteenth Report on the Erratic Blocks of England, Wales, and Ireland;—Third Report on the Fossil Phyllopoda of the Palæozoic Rocks;—Fifth Report on the Earthquake Phenomena of Japan;—Eleventh Report on the Circulation of Underground Waters in the Permeable Formations of England and Wales, and the Quantity and Character of the Water supplied to various Towns and Districts from these Formations;—Report on the Volcanic Phenomena of Vesuvius;—Report on the Fossil Plants of the Tertiary and Secondary Beds of the United Kingdom;—Report on the Rate of Erosion of the Sea-coasts of England and Wales, and the Influence of the Artificial Abstraction of Shingle or other material in that action;—Report on the occupation of a Table at the Zoological Station at Naples;—Report of the Committee for promoting the Establishment of a Marine Biological Station at Granton, Scotland;—Report on the Aid given by the Dominion Government and the Government of the United States to the Encouragement of Fisheries, and to the Investigation of the various forms of Marine Life on the coasts and rivers of North America;—Report of the Committee for promoting the Establishment of Marine Biological Stations on the coast of the United Kingdom;—Report on recent Polyzoa;—Third Report on the Exploration of Kilima-njaro and the adjoining mountains of Equatorial Africa;—Report on the Migration of Birds;—Report of the Committee for furthering the

Exploration of New Guinea by making a grant to Mr. Forbes for the purposes of his Expedition;—Report of the Committee for furthering the Scientific Examination of the country in the vicinity of Mount Roraima in Guiana by making a grant to Mr. Everard F. im Thurn for the purposes of his Expedition;—Report of the Committee for promoting the Survey of Palestine;—Report on the Teaching of Science in Elementary Schools;—Report on Patent Legislation;—Report of the Committee for investigating and publishing reports on the physical characters, languages, and industrial and social condition of the North-Western Tribes of the Dominion of Canada;—Report of the Corresponding Societies Committee;—On Electrolysis;—A tabular statement of the dates at which, and the localities where Pumice or Volcanic Dust was seen in the Indian Ocean in 1883–4;—List of Works on the Geology, Mineralogy, and Palæontology of Staffordshire, Worcestershire, and Warwickshire;—On Slaty Cleavage and allied Rock-Structures, with special reference to the Mechanical Theories of their Origin;—On the Strength of Telegraph Poles;—On the Use of Index Numbers in the Investigation of Trade Statistics;—The Forth Bridge Works;—Electric Lighting at the Forth Bridge Works;—The New Tay Viaduct.

Together with the Transactions of the Sections, Sir Lyon Playfair's Address, and Recommendations of the Association and its Committees.

REPORT OF THE FIFTY-SIXTH MEETING, at Birmingham, September 1886, *Published at £1 4s.*

CONTENTS:—Report on Standards of Light;—Report of the Committee for preparing Instructions for the practical work of Tidal Observation, and Fourth Report on the Harmonic Analysis of Tidal Observations;—Report of the Committee for co-operating with the Scottish Meteorological Society in making Meteorological Observations on Ben Nevis;—Third Report on the best methods of recording the Direct Intensity of Solar Radiation;—Second Report on the best means of Comparing and Reducing Magnetic Observations;—First Report on our Experimental Knowledge of the Properties of Matter with respect to Volume, Pressure, Temperature, and Specific Heat;—Third Report of the Committee for co-operating with Mr. E. J. Lowe in his project of establishing a Meteorological Observatory near Chepstow on a permanent and scientific basis;—Report of the Committee for inviting designs for a good Differential Gravity Meter in supersession of the Pendulum;—Report of the Committee for constructing and issuing practical Standards for use in Electrical Measurements;—Second Report of the Committee for promoting Tidal Observations in Canada;—Report of the Committee for the reduction and tabulation of Tidal Observations in the English Channel, made with the Dover Tide-gauge, and for connecting them with Observations made on the French Coast;—Report of the Committee for preparing a new series of Wave-length Tables of the Spectra of the Elements;—Second Report of the Committee for investigating the subject of Vapour Pressures and Refractive Indices of Salt Solutions;—Second Report of the Committee for investigating certain Physical Constants of Solution, especially the Expansion of Saline Solutions;—Report (provisional) on the influence of the Silent Discharge of Electricity on Oxygen and other Gases;—Report on Isomeric Naphthalene Derivatives;—Report on the Exploration of the Caves of North Wales;—Fourteenth Report on the Erratic Blocks of England, Wales, and Ireland;—Report on the Volcanic Phenomena of Vesuvius and its neighbourhood;—Fourth Report on the Fossil Phyllopoda of the Palæozoic Rocks;—Twelfth Report on the Circulation of Underground Waters in the Permeable Formations of England and Wales, and the Quantity and Character of the Water supplied to various Towns and Districts from these Formations;—Second Report on the Fossil Plants of the Tertiary and Secondary Beds of the United Kingdom;—Report on the Mechanism of the Secretion of Urine;—Report of the Committee for promoting the establishment of a Marine Biological Station at Granton, Scotland;—Report on the occupation of a Table at the Zoological Station at Naples;—Report on the Migration of Birds;—Report of the Committee for continuing the Researches on Food-Fishes and Invertebrates at the St. Andrews Marine Laboratory;—Report on the Depth of the Permanently Frozen Soil in the Polar Regions, its Geographical Limits and relation to the Pole of greatest cold;—Report of the Committee for taking into consideration the Combination of the Ordnance and Admiralty Surveys, and the Production of a Bathy-hypsographical Map of the British Isles;—Report of the Committee for drawing attention to the desirability of further Research in the Antarctic Regions;—Report on the teaching of Science in Ele-

mentary Schools;—Report on the Regulation of Wages by means of Sliding Scales;—Report on the Endurance of Metals under repeated and varying Stresses, and the proper working Stresses on Railway Bridges and other structures subject to varying loads;—Report on the Prehistoric Race in the Greek Islands;—Report of the Committee for investigating and publishing reports on the physical characters, languages, and industrial and social condition of the North-western Tribes of the Dominion of Canada;—Report to the Council of the Corresponding Societies Committee;—Report on Electrolysis in its Physical and Chemical Bearings;—Sixth Report on the Volcanic Phenomena of Japan;—Second Report on the Rate of Erosion of the Sea-coasts of England and Wales, and the Influence of the Artificial Abstraction of Shingle or other Material in that action;—The Modern Development of Thomas Young's Theory of Colour-vision;—On the Explicit Form of the Complete Cubic Differential Resolvent;—On the Phenomena and Theories of Solution;—On the Exploration of the Raygill Fissure in Lothersdale, Yorkshire;—An Accurate and Rapid Method of estimating the Silica in an Igneous Rock:—On some Points for the Consideration of English Engineers with reference to the Design of Girder Bridges;—The Sphere and Roller Mechanism for Transmitting Power;—On Improvements in Electric Safety Lamps;—On the Birmingham, Tame, and Rea District Drainage.

Together with the Transactions of the Sections, Sir J. William Dawson's Address, and Recommendations of the Association and its Committees.

REPORT OF THE FIFTY-SEVENTH MEETING, at Manchester, August and September 1887, *Published at £1 4s.*

CONTENTS :—Third Report of the Committee for promoting Tidal Observations in Canada;—Fourth Report on the best methods of recording the direct Intensity of Solar Radiation;—Report of the Committee for co-operating with the Scottish Meteorological Society in making Meteorological Observations on Ben Nevis;—Fourth Report of the Committee for co-operating with Mr. E. J. Lowe in his project of establishing on a permanent and scientific basis a Meteorological Observatory near Chepstow;—Final Report of the Committee for co-operating with the Meteorological Society of the Mauritius in the publication of Daily Synoptic Charts of the Indian Ocean for the year 1861;—Second Report of the Committee for inviting designs for a good Differential Gravity Meter in supersession of the Pendulum;—Report on the desirability of combined action for the purpose of Translation of Foreign Memoirs;—Report on the Action of the Silent Discharge of Electricity on Oxygen and other Gases;—Report on the Influence of Silicon on the properties of Steel;—Third Report on Standards of Light;—Third Report on certain Physical Constants of Solution, especially the Expansion of Saline Solutions;—Report on the Nature of Solution;—Report on the Bibliography of Solution;—Report of the Committee for making arrangements for assisting the Marine Biological Association Laboratory at Plymouth;—Fifth Report on the Fossil Phyllopoda of the Palæozoic Rocks;—Report on the Migration of Birds;—Report on the Flora and Fauna of the Cameroons Mountain;—Report on the occupation of a Table at the Zoological Station at Naples;—Report of the Committee for aiding in the maintenance of the establishment of a Marine Biological Station at Granton, Scotland;—Report of the Committee for continuing the preparation of a Report on our present knowledge of the Flora of China;—Report on the question of accurately defining the term 'British' as applied to the Marine Fauna and Flora of our Islands;—Report of the Committee for taking steps for the establishment of a Botanical Station at Peradeniya, Ceylon;—Report on the Provincial Museums of the United Kingdom;—First Report on the Disappearance of Native Plants from their Local Habitats;—Report on the Mechanism of the Secretion of Urine;—Report on the Herds of Wild Cattle in Chartley Park and other parks in Great Britain;—Report on the Physiology of the Lymphatic System;—Report on the Depth of Permanently Frozen Soil in the Polar Regions, its Geographical Limits and relation to the present poles of greatest cold;—Report of the Committee for co-operating with the Royal Geographical Society in endeavouring to bring before the authorities of the Universities of Oxford and Cambridge the advisability of promoting the study of Geography by establishing special Chairs for the purpose;—Final Report of the Committee for considering the combination of the Ordnance and Admiralty Surveys, and the production of a Bathy-hypsographical Map of the British Islands;—Report on the teaching of Science in Elementary Schools;—Report on the Prehistoric Inhabitants of the British Islands;—Report of the Committee for editing

a new Edition of 'Anthropological Notes and Queries';—Third Report on the North-Western Tribes of the Dominion of Canada;—Second Report on the Prehistoric Race in the Greek Islands;—Report of the Committee for constructing and issuing practical Standards for use in Electrical Measurements;—Supplement to a Report on Optical Theories;—First Report on the 'Manure' Gravels of Wexford;—Seventh Report on the Volcanic Phenomena of Japan;—Report on the Volcanic Phenomena of Vesuvius and its neighbourhood;—Third Report on the Fossil Plants of the Tertiary and Secondary Beds of the United Kingdom;—Report on the Microscopical Examination of the Older Rocks of Anglesey;—Second Report on Isomeric Naphthalene Derivatives;—Report on the Carboniferous Flora of Halifax and its neighbourhood;—Fifteenth Report on the Erratic Blocks of England, Wales, and Ireland;—Report on the best methods of ascertaining and measuring Variations in the Value of the Monetary Standard;—Second Report on the Cae Gwynn Cave, North Wales;—Report on the Regulation of Wages by means of Lists in the Cotton Industry;—Third Report on the best means of comparing and reducing Magnetic Observations;—Second Report on Electrolysis in its Physical and Chemical Bearings;—Thirteenth Report on the Circulation of Underground Waters in the Permeable Formations of England and Wales, and the Quantity and Character of the Water supplied to various Towns and Districts from these Formations;—Report on the Higher Eocene Beds of the Isle of Wight;—Report on the Endurance of Metals under repeated and varying stresses, and the proper working stresses on Railway Bridges and other structures subject to varying loads;—Report of the Committee for procuring Racial Photographs from the Ancient Egyptian Pictures and Sculptures;—Report of the Corresponding Societies Committee;—On the Vortex Theory of the Luminiferous Æther;—On the Theory of Electric Endosmose and other Allied Phenomena, and on the Existence of a Sliding Coefficient for a Fluid in contact with a Solid;—Gold and Silver: their Geological Distribution and their Probable Future Production;—Recent Illustrations of the Theory of Rent, and their Effect on the Value of Land;—On certain Laws relating to the Régime of Rivers and Estuaries, and on the possibility of Experiments on a small scale;—Experiments on the Mechanical Equivalent of Heat on a large scale;—On an Electric Current Meter.

Together with the Transactions of the Sections, Sir H. E. Roscoe's Address, and Recommendations of the Association and its Committees.

BRITISH ASSOCIATION
FOR
THE ADVANCEMENT OF SCIENCE.

LIST
OF
OFFICERS, COUNCIL, AND MEMBERS,

CORRECTED TO FEBRUARY 1, 1889.

[*Office of the Association:—22 Albemarle Street, London, W.*]

LIST OF MEMBERS

OF THE

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

1889.

- * indicates Life Members entitled to the Annual Report.
 - § indicates Annual Subscribers entitled to the Annual Report.
 - † indicates Subscribers not entitled to the Annual Report.
 - Names without any mark before them are Life Members not entitled to the Annual Report.
 - Names of Members of the GENERAL COMMITTEE are printed in SMALL CAPITALS.
 - Names of Members whose addresses are incomplete or not known are in *italics*.
-

Notice of changes of residence should be sent to the Secretary, 22 Albemarle Street, London, W.

Year of
Election.

- 1887. *Abbe, Cleveland. Weather Bureau, Army Signal Office, Washington, U.S.A.
- 1881. *Abbott, R. T. G. Quarry Cottage, Norton, Malton.
- 1887. †Abbott, T. C. Eastleigh, Queen's-road, Bowdon, Cheshire.
- 1863. *ABEL, Sir FREDERICK AUGUSTUS, O.B., D.C.L., F.R.S., F.C.S., President of the Government Committee on Explosives. Royal Arsenal, Woolwich.
- 1856. †Abercrombie, John, M.D. 39 Welbeck-street, London, W.
- 1886. §ABERCROMBY, The Hon. RALPH, F.R.Met.Soc. 21 Chapel-street, Belgrave-square, London, S.W.
- 1885. *ABERDEEN, The Right Hon. the Earl of, LL.D. 37 Grosvenor-square, London, W.
- 1885. †Aberdeen, The Countess of. 37 Grosvenor-square, London, W.
- 1885. †Abernethy, David W. Ferryhill Cottage, Aberdeen.
- 1863. *ABERNETHY, JAMES, M.Inst.C.E., F.R.S.E. 4 Delahay-street, Westminster, S.W.
- 1885. †Abernethy, James W. 2 Rubislaw-place, Aberdeen.
- 1873. *ABNEY, Captain W. DE W., R.E., C.B., F.R.S., F.R.S.E., F.R.A.S., F.C.S. Willeslie House, Wetherby-road, South Kensington, London, S.W.

Year of
Election.

1886. § Abraham, Harry. 147 High-street, Southampton.
1877. † Ace, Rev. Daniel, D.D., F.R.A.S. Laughton, near Gainsborough, Lincolnshire.

1884. †York, Frederick. 87 Lancaster-road, Notting Hill, London, W.
1886. *YOUNG, A. H., M.B., F.R.C.S., Professor of Anatomy in Owens College, Manchester.
1884. †Young, Frederick. 5 Queensberry-place, London, S.W.
1884. †Young, Professor George Paxton. 121 Bloor-street, Toronto, Canada.
1876. †YOUNG, JOHN, M.D., Professor of Natural History in the University of Glasgow. 38 Cecil-street, Hillhead, Glasgow.
1885. †Young, R. Bruce. 8 Crown-gardens, Dowanhill, Glasgow.
1886. §Young, R. Fisher. New Barnet, Herts.
1883. *YOUNG SYDNEY, D.Sc.. University College, Bristol.
1887. §Young, Sydney. 29 Mark-lane, London, E.C.
1868. †Youngs, John. Richmond Hill, Norwich.
1876. †Yuille, Andrew. 7 Sardinia-terrace, Hillhead, Glasgow.

CORRESPONDING MEMBERS.

Year of
Election.

1871. HIS IMPERIAL MAJESTY THE EMPEROR OF THE BRAZILS.
 1887. Cleveland Abbe. Weather Bureau of the Army Signal Office, Washington, U.S.A.
 1881. Professor G. F. Barker. University of Pennsylvania, Philadelphia, United States.
 1870. Professor Van Beneden, LL.D. Louvain, Belgium.
 1887. Professor A. Bernthsen, Ph.D., Mannheim, L 14, 4, Germany.
 1880. Professor Ludwig Boltzmann. Halbärtgasse, 1, Grätz, Austria.
 1887. His Excellency R. Bonghi. Rome.
 1887. Professor Lewis Boss. Dudley Observatory, Albany, New York, United States.
 1884. Professor H. P. Bowditch, M.D. Boston, Massachusetts, United States.
 1884. Professor George J. Brush. Yale College, New Haven, United States.
 1887. Professor J. W. Bruhl. Freiburg.
 1864. Dr. H. D. Buys-Ballot, Superintendent of the Royal Meteorological Institute of the Netherlands. Utrecht, Holland.
 1887. Professor G. Capellini. Royal University of Bologna.
 1887. Professor J. B. Carnoy. Louvain.
 1887. H. Caro. Mannheim.
 1861. Dr. Carus. Leipzig.
 1887. F. W. Clarke. United States Geological Survey, Washington, United States.
 1855. Dr. Ferdinand Cohn. Breslau, Prussia.
 1871. Professor Dr. Colding. Copenhagen.
 1881. Professor Josiah P. Cooke. Harvard University, United States.
 1873. Professor Guido Cora. 74 Corso Vittorio Emanuele, Turin.
 1880. Professor Cornu. L'École Polytechnique, Paris.
 1870. J. M. Crafts, M.D. L'École des Mines, Paris.
 1876. Professor Luigi Cremona. The University, Rome.
 1889. W. H. Dall. United States Geological Survey, Washington, United States.
 1866. Dr. Geheimrath von Dechen. Bonn.
 1862. Wilhelm Delffs, Professor of Chemistry in the University of Heidelberg.
 1864. M. Des Cloizeaux. Rue Monsieur, 13, Paris.
 1872. Professor G. Dewalque. Liège, Belgium.
 1870. Dr. Anton Dohrn. Naples.
 1882. Dr. Emil Du Bois-Reymond, Professor of Physiology. The University, Berlin.
 1876. Professor Alberto Eccher. Florence.
 1874. Dr. W. Feddersen. Leipzig.

Year of
Election.

1886. Dr. Otto Finsch. Bremen.
 1887. Professor R. Fittig. Strasburg.
 1872. W. de Fonvielle. 50 Rue des Abbesses, Paris.
 1856. Professor E. Frémy. L'Institut, Paris.
 1887. Dr. Anton Fritsch. Prague.
 1881. C. M. Gariel, Secretary of the French Association for the Advancement of Science. 4 Rue Antoine Dubois, Paris.
 1866. Dr. Gaudry. Paris.
 1861. Dr. Geinitz, Professor of Mineralogy and Geology. Dresden.
 1884. Professor J. Willard Gibbs. Yale College, New Haven, United States.
 1884. Professor Wolcott Gibbs. Harvard University, Cambridge, Massachusetts, United States.
 1889. G. K. Gilbert. United States Geological Survey, Washington, United States.
 1870. William Gilpin. Denver, Colorado, United States.
 1876. Dr. Benjamin A. Gould. Cambridge, Massachusetts, United States.
 1884. Major A. W. Greely. Washington, United States.
 1862. Dr. D. Bierens de Haan, Member of the Royal Academy of Sciences, Amsterdam. Leiden, Holland.
 1876. Professor Ernst Haeckel. Jena.
 1889. Horatio Hale. Clinton, Ontario, Canada.
 1881. Dr. Edwin H. Hall. Baltimore, United States.
 1872. Professor James Hall. Albany, State of New York.
 1881. M. Halphen. 21 Rue Ste. Anne, Paris.
 1889. Dr. Max von Hantken. Budapesth.
 1864. M. Hébert, Professor of Geology in the Sorbonne, Paris.
 1887. Fr. von Hefner-Alteneck. Berlin.
 1877. Professor H. L. F. von Helmholtz. Berlin.
 1872. J. E. Hilgard, Assist.-Supt. U.S. Coast Survey. Washington, United States.
 1887. Professor W. His. Leipzig.
 1887. S. Dana Horton. New York.
 1881. Dr. A. A. W. Hubrecht. Leiden.
 1887. Dr. Oliver W. Huntington. Harvard University, Cambridge, Massachusetts, United States.
 1884. Professor C. Loring Jackson. Harvard University, Cambridge, Massachusetts, United States.
 1867. Dr. Janssen, LL.D. The Observatory, Meudon, Seine-et-Oise.
 1876. Dr. W. J. Janssen. Davos-Doerfli, Graubunden, Switzerland.
 1862. Charles Jessen, Med. et Phil. Dr. Kastanienallee, 69, Berlin.
 1881. W. Woolsey Johnson, Professor of Mathematics in the United States Naval Academy. Annapolis, United States.
 1887. Professor C. Julin. Liège.
 1876. Dr. Giuseppe Jung. 7 Via Principe Umberto, Milan.
 1877. M. Akin Karoly. 92 Rue Richelieu, Paris.
 1862. Aug. Kekulé, Professor of Chemistry. Bonn.
 1884. Professor Dairoku Kikuchi, M.A. Imperial University, Tokyo, Japan.
 1873. Dr. Felix Klein. The University, Leipzig.
 1874. Dr. Knoblauch. Halle, Germany.
 1856. Professor A. Kölliker. Wurzburg, Bavaria.
 1887. Dr. Arthur König. The University, Berlin.
 1887. Professor Krause. Göttingen.
 1877. Dr. Hugo Kronecker, Professor of Physiology. The University, Bern, Switzerland.
 1887. Lieutenant R. Kund. German African Society, Berlin.
 1887. Professor A. Ladenburg. Kiel.

Year of
Election.

1887. Professor J. W. Langley. Michigan, United States
 1882. Professor S. P. Langley, LL.D., Secretary of the Smithsonian Institution, Washington, United States.
 1887. Professor Count von Laubach. Göttingen.
 1887. Dr. Leeds, Professor of Chemistry at the Stevens Institute, Hoboken, New Jersey, United States.
 1872. M. Georges Lemoine. 76 Rue d'Assas, Paris.
 1887. Professor A. Lieben. Vienna.
 1883. Dr. F. Lindemann, Professor of Mathematics in the University of Königsberg.
 1877. Dr. M. Lindemann, Hon. Sec. of the Bremen Geographical Society, Bremen.
 1887. Professor G. Lippmann. Paris.
